## ABOUT THE PRIMITIVE-SKILLS-GROUP

-----  
Hello and thank you for your interest in the Primitive-Skills-Group!

The main purpose of this group is to provide a way by which all lovers of primitive skills can discuss various subjects related to wilderness ways.

We have chosen to call it the Primitive Skills Group because whether we are discussing primitive wilderness skills or modern survival skills, we still draw our inspiration and basic knowledge from primitive people who have survived for thousands of years using only what nature provided. Primitive literally means 'first' or 'earliest', therefore primitive and survival skills are our common heritage. The purpose of the group is to share knowledge about this common heritage which can inspire us and comfort us today.

The group was formed in December 1996 by Dr André-François Bourbeau, professor of outdoor pursuits at the University of Québec. Benjamin Pressley (Tribe), Ted E. Bailey (Boomerang list) and Matthew Rapaport (Thrower list) helped to spark the idea of the group and it's initial orientation. Together with the first few dozen members who signed up (see the first introductions which were sent in), the actual group guidelines were developed and have served to orient the discussions since then.

We are currently approximately 200 members who share common interests in primitive skills. You will find it the ideal place to ask the question that's been begging for an answer for so long...

When you send a question to the group, all of the members receive it. Those that have an answer will reply, and the reply will also be sent to all of the members. Sometimes there will be replies to the replies, and the information gained on each subject is enormous.

Remember! The group is intended for fun, sharing and learning about primitive wilderness survival and living skills. All members are asked to refrain from discussing topics related to specific religious, political, persuasion or ethnic views.

Your participation in the discussions of the Primitive Skills Group is appreciated by all other members! If you are a new member, however, we respectfully request that you read the group guidelines before posting.

Thank you for sharing your own experience and skills with us. After

you observe for a while and decide to stay with us, it is suggested that you post a short auto-biographical intro about yourself. Also, you may wish to read some or all of our archives and previous introductions to obtain a better understanding of what the group is about.

WELCOME !

-----

PRIMITIVE SKILLS GROUP GUIDELINES

=====

ALL NEW MEMBERS ARE ASKED TO READ THE FOLLOWING GUIDELINES CAREFULLY!

To communicate with the group, send an E-mail with your message or question to:

Primitive-Skills-Group@uqac.quebec.ca

PURPOSE OF THE GROUP

-----

The main purpose of this group is to provide a way by which all lovers of primitive skills can discuss various subjects related to wilderness ways.

TOPICS TO BE DISCUSSED

-----

Topics which you are ENCOURAGED to discuss with other group members are:

1. All primitive wilderness living skills such as shelter, fire, cordage, primitive tanning, natural foods, primitive living, primitive rafts & boats, primitive direction finding, primitive trapping techniques, weapons for wilderness survival, primitive hygiene, protection from insects, primitive weather prediction, fighting cold, primitive medicine, traditional dog sledding etc.
2. Subjects related to modern realistic wilderness survival, such as surviving when lost in the wilderness, or surviving unexpected emergencies after airplane crashes, broken down snowmobiles etc. , are also welcome.

Please note:

Discussions should be restricted to PRIMITIVE SKILLS only.

By SKILLS discussion, we mean sharing "How-to" information which help group members learn how to accomplish a particular physical task which is useful in a wilderness setting.

By PRIMITIVE discussion, we mean sharing info on skills which are possible in the short term using only materials found in nature, or at least available in the average recreational hiker's backpack.

Topics which you are DISCOURAGED from discussing with other group members are:

1. Topics dealing with religious, spiritual, persuasion, or belief-based concerns. For example, we do NOT wish to discuss subjects dealing with dowsing, natural apparitions, psychology, philosophy, gurus, prophets, spiritual leaders, or the particular styles or approaches of any particular survival expert.

2. Topics dealing with warfare. For example, we do NOT wish to discuss subjects dealing with explosives, survival fighting, revenge, combat methods, and so on.

3. Topics dealing with political or environmental issues. For example, we do NOT wish to discuss subjects dealing with whether it is right or wrong to kill animals, or whether a wilderness area should be protected, and so on.

All members are asked to help "enforce" the above guidelines with regards to topics of discussion.

#### ADVERTISING

-----

1. Unsolicited advertising of any kind by non-members will be severely frowned upon by all group members.
2. Unsolicited advertising of a service or product by members which is DIRECTLY RELATED to primitive skills may be acceptable as long as it is sent ONCE ONLY and for informational purposes only.
3. In direct answer to a question, reference to commercial sources of information, services or products is OK.
4. Personal opinion or judgment of members on a particular commercial product or service is much preferred to sending advertisement on same.

#### GROUP NETIQUETTE

-----

This is a high volume list, and current group members have asked that the following etiquette guidelines be followed whenever possible:

1. Please always rename subject headers when replying so that the header always matches the content of the message (helps store archives).
2. Please stick to one subject per message (helps store archives).
3. Please send "I agree with you", "Thank you", and "Bravo" messages which have no actual content through private E-mail (these are important, but clutter the list too much).
4. When replying, please quote only the passage which permits to follow the discussion, not the entire previous message (facilitates reading replies).
5. Note that there are two Reply-to addresses when you send a reply. One for the group, and one for the sender. Please delete one of the two (so the sender doesn't receive double messages).
6. Please keep signature files as small as possible (4-5 lines max).
7. Please avoid sending "funnies only" messages to the group. We all

appreciate a good joke, and even more so when it is part of a message which has content too (prevents list clutter).

8. Please read at least the primitive-skills archive headers so you don't ask a question which has already been answered.

9. It is a good idea to read the introductions archive so you have an idea of who's who in the group.

The archives can be found at the following location:

<http://pages.infinet.net/afb/priskarl.htm>

#### COMMANDS

-----

The following commands are available by sending an E-mail message to:

[listserv@uqac.quebec.ca](mailto:listserv@uqac.quebec.ca)

SUBSCRIBE Primitive-Skills-Group (to subscribe to mailing list)  
SIGNOFF Primitive-Skills-Group (to remove yourself from mailing list)  
REVIEW Primitive-Skills-Group (to get a list of subscribers)  
QUERY Primitive-Skills-Group (to get the status of your list entry)  
SET Primitive-Skills-Group NOMAIL (to remain a member but not get mail)  
SET Primitive-Skills-Group MAIL (to reverse the NOMAIL setting)  
SET Primitive-Skills-Group NOREPRO (to prevent receiving your own posts)  
SET Primitive-Skills-Group REPRO (to reverse the NOREPRO setting)  
HELP (to receive a help file)

Put the command in the body of the E-mail (nothing else). The subject header will be disregarded.

Digest-mode is NOT available yet, sorry.

#### UNSUBSCRIBING

-----

Please save the following information!

To unsubscribe, you must send an E-mail with the following command in the body of the message (nothing else):

SIGNOFF Primitive-Skills-Group

The header will be ignored. Send the message to this address (NOT to the group):

[listserv@uqac.quebec.ca](mailto:listserv@uqac.quebec.ca)

#### QUESTIONS OR COMMENTS

-----  
Any questions or comments are welcome and can be addressed to the  
list manager:

mailto: bourbeau@videotron.ca

-----  
-----  
End of file  
Thanks for reading...

PRIMITIVE SKILLS GROUP-- INTRODUCTIONS

This is a list of the introductions sent to the primitive skills group by some of the members. The introductions are listed in the order in which they were received. This file can help you feel at home by learning about some of the people which make up the group. If you would like your name added to this list (or removed) or if you would like to change the content, just let me know.

André-François Bourbeau  
List manager

[bourbeau@videotron.qc.ca](mailto:bourbeau@videotron.qc.ca)

-----  
-----

André-François Bourbeau

Hi everyone, my name is André-François Bourbeau and I'm a professor at the University of Québec, Chicoutimi campus, where I teach outdoor pursuits in an adventure tourism bachelor's degree. This 3 year program is in french, so unfortunately much of the material I have developed will have to be translated before it is useful to many of you- sorry about that. I have been at the university for 15 years now, teaching courses such as winter camping, whitewater canoeing, wilderness survival, outdoor leadership, environmental awareness, philosophy of outdoor education and such. I also have research duties, and my field of interest is "coureur de bois" and primitive wilderness survival. I did my doctoral thesis on how to write clear instructions for primitive wilderness survival techniques in 1984. Since then, my research methods have been largely experiential: basically, I put myself in simulated situations in order to learn about old ways and develop new knowledge.

I conducted two major trips, one was a 31 day experiment in 1984 where I was dropped by helicopter on the 50th parallel without food, without fire, without tools, without shelter- just the light clothes on my back. That was a pretty rough trip, details of which are to be found in a book I wrote about the experience entitled "Survie au Gré de la Nature"- sorry, only available in french for now. The book is a day by day report on the trip, to which was added a scientific report on various subjects studied during the experiment.

The other major trip I did was in 1988, a 40 day reconstruction of a trip along the fur trade route in the year 1838. All the materials used were authentic reproductions of the period's gear, including real birchbark canoes and even handsewn underwear. This trip is documented in a film by KEG productions of Toronto called "Man of the Wilderness" which has been translated into many languages and has been shown on many television networks around the world.

My main interests are in developing wilderness survival techniques for someone lost or downed in the boreal type forest. All ideas I find from other parts of the world I try to adapt to materials found here.

For example, fire saws are possible with bamboo- I try to find materials to make it work here.

I am really looking forward to all the fine discussions I am certain will develop as the Primitive Skills Group grows. By the way, I am the list manager for the group, so any concerns you may have about the way the group functions can be addressed directly to me.

I'm looking forward to exchanging with all of you.

Thank you,

André-François Bourbeau  
bourbeau@videotron.qc.ca

-----  
----

Benjamin Pressley

My name is Benjamin Pressley. I teach primitive, survival and wilderness living skills. I write for several magazines like American Survival Guide, Backwoodsman and Wilderness Way. I co-founded an organization called TRIBE that now has members in 46 states, Canada, New Guinea and Guam. I publish a newsletter for TRIBE also that many of you will find interesting, I'm sure. We are a network that operates non-profit to connect people interested in primitive skills with resources and other people. I am skilled in many areas of primitive skills. Shelter building, fire making, water sources, some edible and medicinal plant knowledge (enough to get by), tools from stone, shell, bone and wood, braintanning animal hides, traps and snares, fishing technologies, cordage making, lighting methods, cooking without aid of modern utensils, and much more. Hunting Weaponry is particularly an interest of mine. I teach classes year-round and do a lot of demonstrations for schools, museums, etc. The particular weapons that my research has been in are slings, bolas, atlatls, non-returning throwing sticks, blow guns. I will be glad to help out anyway I can with questions, etc. If you are interested in primitive, survival and wilderness living skills that I have please inquire. My skills are based on skills used by primitive people for thousands (more?) of years. If you want more information about our organization, TRIBE, check out: <http://users.aol.com/tbprim1/Tribe.html> Ted Bailey does this homepage for me. As I get more Internet/Web page savvy I plan on putting out a

mini-newsletter for people interested. For now, check out that site and it will tell you more about what we have to offer. Well, enough for now.

I'm looking forward to interacting with everyone in the Primitive Skills

Group list. My thanks to Andre for getting it set up. ---Benjamin (benjamin@perigee.net or tribe@perigee.net)

-----  
----

Matthew Rapaport

Hello... Thank you to Andre for inviting me to participate. I am a classical arm-chair primitive! I enjoy a good camping adventure, and have had a fair number in my youth, but none for a decade or more now. Even these were not primitive living the likes of which our host has experienced, but rather late 20th century American style back-packing which means NOT that you use what is around you to make your way, but that you touch as little as possible! The object as much as possible is to leave the environment as untouched as possible while you pass through it.

I am not a hunter, though I have fished (mostly in salt water). I know how to prepare fish and other sea food, but would like to learn to dress game, even if I don't kill it. I do enjoy shooting with fire arms, and bows however, and could hunt if I had to do it, even with a slingshot. Better I round myself out gaining some experience with traps!

My real interest in bushcraft skills for now is not in wilderness living, but in living more or less comfortably though a period of normal infrastructure and service disruption in my semi-urban environment, typically as a result of some natural disaster like an earthquake! Here what is important is having stocked the right materials in the right quantities in places that survive the initial disaster. If the supermarkets are closed long enough, I may want to fall back on some food finding skills for a while...

I look forward to future conversations.

matthew rapaport          Philosopher/Programmer at large          KD6KVH

-----  
-----

Mark Bradner

Hello group...

I live in the Seattle, area, I've spent a large percentage of my 45 years backpacking and camping in the Pacific North West. So I guess primitive technologies have always interested me. This year I have taken up flintknapping, and I heard about your group from the knapper list server.

Mark Bradner

-----  
-----

Chris Smith

Hello Skills Group,

A very big pleasure and opportunity to learn from and share with you all. These introductory things are always very painful for me, so I hope you don't mind me torturing myself a bit.

My name's Chris Smith, I'm 48 and live in Coeur d'Alene (Core duh'Lane), Idaho, USA. That's near Canada and is a place of big lakes, rivers and forest woodland. I'm pretty happy, even when shoveling snow. I'd rather be in a hot spring than any other place on earth and that's why I live in Idaho. I still work irregardless, and have tended 'premie' babies, down to a 1/2 lb. that will fit in the palm of your hand. I'm a registered Respiratory Therapist with a perinatal/pediatric clinical specialty certification and have similar credentials for practice in Pulmonary Function Technology and Cardiopulmonary Technology. I've worked in the medical field for nearly 25 yrs, and I guess I've also worked with more knife and gunshot wound victims than most people. Not my cup of tea, anyway, my educational record is bizarre, with three 2 yr. Associate degrees and quite a few unrelated subjects. My transcripts read like: motorcycle repair, biochemistry, concrete, embryology, welding and mukluk making. If there was a degree program in Irreproducible Studies, I'd have my Masters. I've been politely and personally asked to immediately leave nice places by elk, moose, grizzly bear, rock slides, whizzing ball lightning and "the buzzing of the bee's" -- I'm not ashamed to tell you, I am trembling at the thought even now, which makes it all the harder to type. I can't rationally explain why I haven't died all the times I obviously should've, but whoever you are, I want to thank you personally - I recommend you highly to all.

I've been a 60's Haight-Ashbury hippie, an American Marine with an Intelligence occupational specialty (I can't say much about that), have lived in a Zen monastery and used to be a fair rock climber. I still love my my old .45 and Ka-Bar Marine knife (well, it's true) and have a warm fuzzy feeling for shotguns, ancient cultures and the wrath of nature. I like handling bullwhips and throwing knives, tomahawks and axes. I'm a member of the Wild West Arts Club, a 600 member international stunt organization. I'm not all that good, but I do play. I've wanted to learn multi-strand braiding since I was a child and through the Thrower list have begun sling braiding which covers that nicely. Kind of a sportman's paradise where I live, so if you asked me to spear you a fish, I probably could handle it. I've been fortunate to meet and sometimes carea few celebrities, including Groucho Marx, Carole King and one large hawk in particular. I have the highest respect for people like yourselves (I know what I'm talking about here) and appreciate your company and experience, which is considerable. Thanks.

Chris

-----  
-----

Ted E. Bailey

Hi Everybody. I just subscribed to the Primitive Skills Group today. I found Chris' introduction quite interesting. I was a Haight Ashbury hippie too and I just a year younger. Chris, did we meet in the Fillmore West over New Year's in 1968?

Anyway, I am quite straight now. I even have short hair and I am an Engineering Manager. Now you know what happened to all those hippies! My favorite hobby is boomerangs and throwsticks. I got into this primitive skills stuff as a young child growing up in Panama. The first toys I wanted my Mom and Dad to buy were the blow guns and shrunken heads that the Choco Indians sold at the border towns. I used to spend all my time in the jungle learning about the native animals and surviving on my own with minimal equipment. When I was 17, I left Panama and went to Arcata California to go to college. That was the beginning of my hippy days. 10 years later, I came out of the fog with a MS degree in Mechanical Engineering and I have been stuck in a middle class rut ever since. I throw boomerangs and put out a boomerang newsletter to keep me

busy. I belong to the boomerang rang\_list and the thrower email subscription group as well. I look forward to hearign more about the other subscribers. Cheers. - Ted

-----  
-----  
Alexander J. Pirchl

About me: I live in Austria (Europ), particulary in Kitzbuehle in the Tyrolian mountains. I am 23 years old and married now for 1 1/2 years. I have always been fascinated by \*primitiv\* technology and weapons. Since I was very small I have been toying around with knives, spears, blowguns, slingshots and slings. I also like all aspects of shooting, and owe quit a number of firearms, but the power and accuracy one could get with weapons made from the simpelest components have never ceased to amaze me. Survival is also a topic which I find very interesting, and the question of another member of this list stated in his introduction on what to stock up for a naural desaster would interest me very much.

-----  
-----  
Merv Martin

Hi

I'm Merv (Mervyn Martin). I was born in Red Bluff, California and lack the strip between Izmir, Turkey and Taipei, Taiwan of having been around the world.

I'm ex-Navy (14 years, that's how I got to travel) and now work, when I can find it, as an Electronics Engineer in Sacramento, CA. What else, oh, I'm 45 and have just taken on two more kids, a 15 year old boy and a 12 year old girl. What a glutton for punishment (that makes five kids)!!! Ah well, I'm half adopted too and I like my step dad!

I'm fascinated with anything I can do with my hands. In the past I've done well at surviving with a knife. I say well, I gained

weight. I'm a pretty good trapper and only scruple at swallowing uncooked bones. They're a bit scratchy (in and out). I can't say that I've tried grubs, but Caddis Fly larvae and Helgramites aren't bad. I've fished with, but not eaten Stone Fly Larvae (Toebiters). Always wondered who'd get the most bites. Salmon eggs aren't bad either, haven't tried frog eggs.

I've info that may be of use. Like how to build a rope walk (a "machine" for the manufacture of rope). I'll need to dig out the text for that, it's an old Aussie book called "Bushcraft".

Wow! Primitive Skills! Anybody wanna go fishing? Hook, Spear or Trap???

BTW, the main reason I can gain weight on a survival test is that I know the area and trap! Spinning cordage would be most important to someone like me. I've used mostly grasses and 1/4 to 1/2 inch thick. This stuff usually will take a jack rabbit (1/2").

Whew, I'd better close for now!

Ya'll Take Care. Looks like a great bunch of crazys here.

Merv

Barent Parslow

Hello all,

I am very pleased to be a part of this group. I am a 23 1/2 year veteran of the US Army currently serving with the Virginia National Guard and will retire in about 2 1/2 years. I am wondering if we are seeing a pattern develop here of the personality types that are interested in this subject?

I was raised by both my own parents, Dad a forester and Mom a teacher and librarian, joined the Army out of high school, was a linguist working in intelligence, also served as a supply sergeant and in the infantry, was literate in Korean and Chinese, semi-literate in French, barely literate in English (especially after 5 years in Korea) and now the computer

guru

for my Brigade (if only they knew how little I really know).

My hobbies include (when I can find the time): archery, hunting, shooting (modern and blackpowder), reloading, running (occupational), swimming, biking, computers, reading (voraciously), history (was my Brigade's historian), and community service.

I am now starting to build primitive bows (an outgrowth of my interest in archery, I have been shooting since I was 10) which lead to an interest in flintknapping (led to this list by post on knappers list), which has led to interest in the subjects this list should be exploring.

Many thanks for starting this list. I hope to learn alot. Also, I would like to say that I don't believe that there is such a thing as a stupid question. No questions, no answers.

I should also let you know that I am a little blunt (not that blunt, did that get sent, if so I apologize) No anger, just a little too straightforward sometimes. Tactless or so some have said.

Sincerely,

Barent

Duty, Honor, Country

parslowb@CFW.COM

-----  
----

James E. Burdine

I am an R.N. that works in a Surgical ICU, but I also have past experience in the E.R. I've been enterested in survival and primitive technology ever since I made my first bow from a cherry branch at the age

of 5 and had the same bow broken over my backside after a shot went wrong.

On my mother's side of the family is Hessian German, and my mother still

talks about the war years and things they did to survive hard times. On my

father's side is Scott/Irish and Am. Indian(either Cherokee or Blackfoot

depending on who you ask) So I am quite happily a mutt. My Dad tell stories

about the big depression, and humorous experiences from his 30 years in the

Army( but would not until recently talk about his experiences in the Korean

war) I've rubbed elbows with some of the finest survivalists in the U.S.

from the Rangers, Special Forces, and Force Recon(who talked to me

even  
though I was a leg army puke) I messed about with throwing knives,  
bows,  
firearms of various types and .38 cal blowguns. I learned to fish, and  
camped with the Boy Scouts. I learned how to make a warm bed in  
nothing but  
a pile of leaves(pile them up,dive in gently, and wait until your body  
heat  
creates a pocket of warmth) What struck me as a disadvantage about  
survivalism is that most people seperated from their kits would not  
be able  
to survive, because older methods of survival had been lost. I felt that  
one should be able to be dropped anywhere in the wilderness and be  
able to  
scrounge up materials needed to sustain life.Thus I started reading  
everything I could find about primitive technology, including what I  
call  
neo primitive technology. Neo- primitive technology is old techniques  
with  
non-traditional materials. For example slingshots use traditional  
bowhunting techniques with a high tech substance (vulcanized rubber)  
or  
using steel tubing to make a blowgun. Well that's enough hot wind for  
now.  
JB

jburdine@PIPELINE.COM (James E. Burdine)

-----  
----  
Russ Brownlow

Hey all,

I too came to this list from the KNAPPER list. My name is Russ  
Brownlow and I've lived in Texas my whole life. Just moved to  
Houston  
after being in Austin for 8 years. I'm pursuing a master's degree in  
archaeology, possibly a PhD after that.

I've been involved in wilderness survival pursuits since I was a kid in  
Scouts. I became an Eagle Scout at 16 and have been roaming the  
wilderness since. I'm not a hardcore militant survivalist, but I  
usually work deep in the woods, so I get along OK. I haven't had to eat  
any bugs to survive though. I'm an archaeologist for a company out of  
Austin, and we do surveys, testing, etc. across the country.

I wasn't around at any of the concerts you guys were talking about,  
but  
I might have been conceived at one of them early in '69. Although I'm  
not a true hippie, I like to think that I would've fit in well back in  
the day.

I work for an environmental firm out of Austin, TX. We do biological as well as cultural resource management type stuff.

Whenever

a pipeline, a transmission line, well pad, coal mine, etc. are planned, we go out and survey the area for any archaeological sites. If we find any "significant" ones, we test them. If testing proves that they are more than just the run of the mill scatters, we often excavate them.

Yes

I've found all sorts of Native artifacts, its pretty much a daily occurrence when

we're out in the field. I also work in the lab were I do whatever has to be done.

My main job in the lab though is the illustration of the artifacts for publication. I'm an archaeologist and an ARTaeologist I guess you could

say. We find lithics and pottery, but no mummies down here. We do have

the occasional burial, but rarely. No signs of weaving since this area of Texas has acidic sandy soil that pretty much dissolves everything that is not rock. As for my "time travels" as an archaeologist, those hopefully lay ahead of me. I've been doing this for a while now, but only for about the past four years professionally (that is, getting paid for it). That is why I'm pursuing higher degrees, otherwise I'm relegated to being a hired shovel bum. I have run several projects, but technically I don't get the credit since the law requires a Master's degree to do so. Soon that will be taken care of. I did go to the Middle East for a while. You can find artifacts there all over the place (just walking down the road). I was chasing a herd of camels in the desert once and found an area where the wind had deflated some dunes. I found several flint cores, some pottery (that dated to around 200 B.C. from Syria), mussel shells from the ocean, and two hearths with

burned bone in them. People have lived there for thousands of years so

I guess it is no surprise that there are artifacts everywhere. I even found an old net weight made of stone washed up on the beach. That is about as extensive as my travels go (oh yeah, I hung out in Amsterdam for a while :] ). Otherwise, I've just travelled all over Texas digging sites. As for the tribes, that is hard to say. Most of the stuff is Archaic or Paleo so we have no idea who the tribes were that far back. Of course some of the upper layers have artifacts usually associated with the Karankawa, Cherokee, Apache, depending where you're at in the

state. Other than that, I'm just the young hippie type trying to make a living by having a good time out in the woods looking for stuff. It's a pretty "groovy" job.

PEACE,

/ Russ \  
( \_ \_ )  
) ( )  
( \_\_\_\_\_ )

Russ & Rebecca Brownlow

-----  
----  
Greg Biddle

Heya all,

First let me introduce myself a little. My name is Greg Biddle, I'm an archeologist, currently working in Juneau AK. I have worked all over quite a bit of the western and midwestern US. I have been flintknapping for about 7-8 years and have been interested in / practicing 'primitive' skills since my uncle taught me how to shoot a bow, bareback from a horse, and how to cure squirrel pelts with table salt (Sorry Mom!?!). I am really enjoying this group, although I was getting a little worried about the 'fish bombing' thread!!

-----  
----  
Sherri Seer

Hi,

Just a brief note to introduce myself. My name is Sherri . I am a licensed emt, hypnotherapist, an ergonomist, scuba diver, licensed ham radio operator (kb8yxg) and am currently taking a course from the Wilderness Awareness School called the Kamana Correspondence Course which will give me a certificate as a Naturalist. Have all of Tom Brown Jr's. tracker books, many herb books. I am interested in all of the old skills. I am attempting to teach myself to live in any environment, for any length of time, starting with no more than a knife and piece of plastic. I love the earth, animals, the wind in my hair, the wilderness, Native American teachings. I am greatly saddened by the mass distruction of the "modern" world ways. It causes a great burden to rest on my soul as I walk along and view it.

I am glad I have found this list and the trackers list in which I can learn & share information.

Many blessings upon us all,  
Sherri

(seer7@dnaco.net)

----  
David McMullen,

Hello fellow primitives

My name is Dave McMullen and I hail from Montreal, Quebec. I am very interested in learning primitives skills of all types. I belong to a skills/craft group called earthlodge (affiliated with a college in the area). Some of the skills that the group has become active in recently have been: flintknapping, atlatl, bowmaking, fire by friction, cordage, native american spirituality.

I am very ghappy to have found a primitive skills group with roots so close to home. Am looking forward to learning as much as I can

Dave McMullen

-----  
Thomas J. Elpel

I am new to the primitive skills group.

We operate Hollowtop Outdoor Primitive School (HOPS) in Pony, Montana. If you would like a brochure of our books and classes send your postal address to tomelpel@3rivers.net. Mailing lists are expensive to maintain, so please ask only if you are seriously interested.

Below is a promotional for one of my books:

Thomas J. Elpel's Field Guide to Primitive Living Skills

Primitive living is a way of learning about nature by participating in nature. Instead of merely camping in the wilderness or passing through it, you can become part of the process. You discover nature by using it to meet your needs for shelter, fire, water, and food.

Tom's guide will give you a direct, hands-on experience of the world around you. With this book you will have the opportunity to discover the thrill of staying warm and comfortable without even a blanket! Experience the magic of starting a fire by friction. Learn about the edible plants of the Rocky Mountain region and the techniques to process

them,  
plus "primitive gourmet" cooking skills. Tan the hides from your fall hunting trip, and manufacture these into durable clothing. Also covered are: primitive bows & arrows, sinews, hide glue, backpacking, felting with wool, fishing by hand, stone knives, wooden containers, willow baskets, twig deer, cordage, stalking skills, trapping, and tire shoes.

Thomas J. Elpel's Field Guide to Primitive Living Skills includes dozens of innovative skills and 160 photographs, plus an encompassing philosophy. Tom does extensive research and development of primitive skills. He places an emphasis on publishing new information that is not found in any other source. The cost is \$17 plus \$3 priority postage. Send check or money order to HOPS, Box 691, Pony, MT 59747 or use your Visa or Master Card and call 406-685-3222.

Watch for more of Tom's writing in these publications:

The Bulletin of Primitive Technology - 2 issues per year, \$25 - Box 905 -

Rexburg, ID 83440.

BackHome - 6 issues per year - Box 70 - Hendersonville, NC 28793.

Wilderness Way - 4 issues per year, \$18 - Box 203 - Lufkin, TX 75902-0203.

The Mother Earth News - 6 issues per year - Box 56304 - Boulder, CO 80323-6304.

As for a personal history, here is a short chronology of my primitive skills background. I spent a great deal of time with my grandmother as a child (I live 2 blocks from her now). We took walks every day and studied plants and plant uses. She had Larry Olsen's book and I linked up with Boulder Outdoor Survival School from there. I went on the 26 day walk-about in 1984, at the age of 16. My Grandmother and I went to Tom Brown's Standard Course in 1985. My cousin Melvin Beattie taught me hide-tanning the same year (I've tanned 60 deer hides, plus elk, antelope, and furs). My fiance (Renee) and I walked 500 miles across Montana in '88, and married in '89. We worked with primitive skills programs for adolescents for a couple years.

I practiced primitive skills as often as I could, and finally reached a point where I had tried most of the general skills, and was still

far from comfortable. Since then I have been doing my own research and experimentation.

For example, I discovered that it was not enough to merely copy shelters from a book, because every shelter should be uniquely designed to fit the time and place and the individual's goals while staying there. I developed innovative new shelter ideas for my area, and more importantly, a thought model for building shelters in any environment.

Botany/herbology is another area where I have conducted new research. Most people are not willing or able to spend decades learning plants and plant uses. The "plant patterns" approach I am using enables the beginning student to cut years off the learning process. Instead of me telling the students about each plant we come to, I give them some patterns to watch for--and ask them questions about the new plants we encounter.

Another innovation I helped develop is a "tire sandal", designed to be worn with moccasins. It is a modular system, so a person can wear just the moccasins for stalking or around camp, or just the tires for wading, or both for hiking and climbing. Moccasins wear out too quickly, and most weekend primitives do not walk barefoot enough to build up the callouses necessary to walk barefoot all the time. Tires may not be a natural resource in the conventional sense, but they are a resource found abundantly in nature. The tire sandals with moccasins make the best shoes I have ever worn, in or out of town.

Six months ago we adopted three children, so we have been putting our energy into becoming a family. The girls are ages 6 and 7, the boy is 2. We are gradually introducing them to the primitive skills. They like to camp in the 23 foot diameter "earthlodge" we built on our place. We are learning American sign language together. After focussing almost entirely on plants for the last two years, I plan to switch back to the "animal skills" this summer. I expect to do a lot of stalking with the kids (one of the reasons for learning sign language).

Always Peace,  
Thomas J. Elpel  
tomelpel@3rivers.net.

Wanita & Joel Sears

Hi, I'm Wanita Sears. Found out about this group from the knapper list. Sorry for the semi intro. It's hard to pin down my hubby, Joel for the computer other than to look at the messages. He is a knapper and spent much of his boyhood in the woods learning survival skills. The medicinal plant threads interest me on this list.

Wanita Sears

Kevin Reeve

I have seen a number of intros flying around and guess I should give a little background about myself. I am approaching my 40th birthday with trepidation. I live in San Jose California with my wife and children, and when I am not practising my skills, I am an organizational consultant. That may sound common, but what is unusual about my consulting is that I apply wilderness skills to organization with interesting and so-far, very positive results.

My interest in survival began as a very young man, continued through Scouting. I was at BYU when Larry Dean Olsen began the program that ultimately became Boulder Outdoor Survival School, and watched that program grow with great interest.

I have been taking classes from Tom Brown for the past 6 years, and for the past three years have edited his newsletter "True Tracks." In '96 I set up and ran his first Standard class (the beginning class) in California.(He came out and did a lot of the teaching.) I will be setting up another Standard and his basic Philosophy class in California in '97. I am also working on other new programs for the school that will be announced in 1997.

I love tracking, enjoy firemaking (hey Bob - I got a fire with a Cattail handdrill!) bow making, tanning, knapping (amatuer), and various other primitive skills. I know several of you who have been posting, and have seen some great stuff so far. I consider myself fortunate to read the postings of such experienced and talented outdoor people. Please keep it up.

Kevin  
-----  
----

Bill Blohm

I'm basically a systems administrator/web-master-in-training at Hewlett-Packard, Boise, Idaho, USA. I grew up an AF brat, and my favorite times were in Alaska, where I could run in the woods as soon as my homework was done. I've done a fair bit of camping, although none of late. Among other hobbies, the pertinent ones would be: navigation (celestial and terrestrial), back country exploring, kayak-touring, canoeing, back country XC-skiing, slings, archery, knives, hunting, fishing, playing with whips (getting there, Chris!), walk-about, climbing, minimal-impact camping/hiking, astronomy, a general interest in primitive skills, snowshoeing, tracking, outdoor photography, stalking (animals and birds, not people! ;-), just shooting, boomerangs, crossbows. Like my wife says, I've got too many hobbies. If it's outdoors, I'm interested.

I'm a totally deaf lip-reader and a ham radio operator.

Bill B. (Bill Blohm)  
bblohm@boi.hp.com

Karen Hood

Hello,

My name is Karen Hood, co-owner of Hoods Woods Wilderness Video Productions. My husband, Dr. Ron Hood and I have just joined your group. I have been a Survival student and instructor for the last 7 years. I'm also co-producer and cameraman for our Woodsmaster wilderness skills videotape series in which Ron teaches various wilderness skills. Ron and I also run private and summer survival trips in the Sierra through our company Hoods Woods. We are very much looking forward to sharing information with others and learning as well. Thank you for inviting us on!!

If you'd like to visit our site and find out about our videos&/or trips,

we're at <http://www.survival.com/~diogenes>

Sincerely,

Karen Hood  
mtnwmn@survival.com

-----  
----  
Ron Hood

Hi Folks!

Thanks to Andre for inviting us to join you! Andre was kind enough to send us some bio information about the group. I guess that it's my turn to share.

Like many of you, I'm a veteran. I was in the U.S. Army Security Agency from 1963 to 1967. I served time (literally! ASA training and duty was NOT romantic or pleasant) in Turkey (11 months and ten days, I counted every minute) assigned to several Kurdish settlers with an occasional rest in Sinop, Turkey. We trekked over much of the country, I still have the scars. On the positive side I gained a respect for some really tough and skilled survivalists.

Not wanting to waste my tolerance for pain, the US Army assigned me to Vietnam. I spent just over 18 months in-country some in the central highlands with the Montegnard tribesmen learning their brand of survival. Trekking in Vietnam is (was) very different from what I'd learned during my stay in Turkey. At the end of my 18th month I was evacuated to Japan.

In Japan, I was given an opportunity to study Judo at the Kodokan in Fukuoka, Japan. An altogether enlightening experience. At this point I was 22 years old. Finally, after much wriggling and whining, the Army let me go.

When I arrived in the states I was a wreck. Three years of hardcore survival certified that I wasn't fit for polite society, no tolerance for quick movement or loud noises. I ran to the mountains. I lived off the land in the Napa, Sonoma, Mendecino counties of California, for six months. My judo training and meditation skills helped me to find sanity again (THAT'S relative!). I entered the job market.

I repossessed cars for awhile. Rented out ski boats, and so on. Then I went back to school.

I got my AA in History

My BA in History

I went to work teaching survival at UCLA and CSUN in 1974

I got my MS in Outdoor recreation

I Quit teaching at UCLA in 1982 and at CSUN in 1992. At that time I was head of the special outdoor programs at CSUN.

During the intervening time I brought the paint ball war games to Southern California, ran our Hoods Woods programs for special groups and private parties and acted as the Technical consultant for a passel of films and TV programs.

In 1991 I finally met someone who could put up with me ..... My wife

Karen.

We were married in our hearts, during a spirit quest, at dawn on top of Templeton Mountain in the Sierra. I've never been happier. Survival skills bring many feelings but this is something I never expected! I finally finished my Doctoral studies last year "A study of system operators in computer mediated electronic communication systems" Pepperdine University. Sorta bizarre considering my background.

Now we (my wife and partner, Karen) and I are producing a series of wilderness survival skills videos, the Woodsmaster series. We are at volume 3 now and working on number four. I've got all this STUFF from the Middle East and Southeast Asia to share. Though the setting for the videos is the Sierra of California, many of the weird techniques I learned will ultimately end up in the videos.

There's more but I don't want to over stay my welcome. There's an old saying "Fish and guests spoil after three days". We can also say that Email spoils after three pages.....

If you have a chance, and the inclination, stop by and visit us!

Hoods Woods... <http://www.survival.com/~diogenes>

Peace,

Ron Hooddiogenes@survival.com

"Doc" Ron

Mr and Mrs Veilleux

I was delighted to find a list closer to home on the subject. I have attended a couple of courses with my husband at the Tom Brown Jr. survival school in New Jersey and am subscribed to their list but often I seek information here in Canada and

find it sometimes hard to track down. ( very good courses: we have taken basic, advanced and Philosophy I, friends of ours also have advanced Tracking )

My own personal area of interest is in primitive foods and medicine. I was

wondering if anyone knows of any? ( french or english ) My husband and I,

as well as some friends, are presently brain tanning some deer and beaver hides.

We are looking forward to sharing ideas and information with everyone.

veilleux@NETCOM.CA

-----  
----  
Wes Gietz

Time to introduce myself, as so many others have done with flair and impressive descriptions of experience.

I'm located in Victoria, BC (currently the snow capital of Canada), and have rediscovered the old ways after about 25 years of focusing on education, family, career, and competitive sports. I spent a lot of time in the bush around Kenora, ON when I was a kid, and it was back there on a winter camping trip with my brother that I was first introduced to Tom Brown Jr.'s books.

Since reading TBJ's books and attending some of his classes I have been practising the skills and following the philosophical path he teaches, and working with an Ojibwa medicine man who lives here. I now teach the ancient skills in workshops as well as occasionally teaching or speaking at conferences, and I conduct sweats.

Wes Gietz

Mark Zanoni

Hi everybody,

I found out about this group from the Tracker list serve and so far I am impressed by the quality of the discussion. I live and work in Northern Wisconsin and run an outdoor program for special ed. (behavior disorder primarily) kids that utilizes primitive skills as a major component.

My vision is to develop an entire curriculum using nature awareness, tracking and primitive skills and other experiential approaches, to teach all areas of study across the board including social studies, science, English, math, art, phy. ed. etc. I'm already well on the way towards making that happen and, luckily I'm in a situation where I am able to experient and work out different aspects of this project as I go.

In addition to my this work I teach wilderness skills workshops that include primitive skills, tracking and nature awarness as part of an organization in Milwaukee called Medicine Hawk wilderness skills. My own organization has given the go ahead for me to begin a series of classes at my Northern WI location also and so this spring I will be offering classes for the general public, family programs and teacher trainings.

My training and background include lots of time playing in the woods as kid (maybe the most valuable part of my training), a college degree in Natural Resources/History, a secondary teaching certification and attendance at classes around the country including Tom Brown's standard course, classes with Charles Worsham in Virginia and everything Tom Hanratty at Medicine Hawk offered until he got tired of seeing my face in class and made me an instructor about 7 years ago. I also learn where I can and I am lucky to live in an area that has an abundance of skilled crafts and outdoors people. My main and most important teacher, however, remains nature itself. I am lucky to have a job that allows me to be in the woods everyday. In fact how many people on this list could say they have a job that requires that they spend time in the woods? I am very blessed I know.

I look forward to sharing with and learning from you all,

Many blessings,

Mark Zanoni

-----  
----  
John Wiedenheft

Hi group! I just signed on; heard about you over in the Tracker list. My name is John Wiedenheft, I live in Norwich Connecticut USA. I have always been interested in primitive skills and wild edibles, ever since being introduced to this stuff by my mother on our family camping trips. She would walk through the woods and pick various plants and we would bring them home and have them for dinner!

I have been camping and hiking ever since (I'm now 40 years old), and picking up new skills wherever I can. Picking up new skills has been a difficult thing to do because I didn't know of any other sources of information. Then, about 5 years ago, I came across a book by Larry Dean Olsen. A year later I was telling someone about that book and he handed me "The Tracker" by Tom Brown. I have now read most of Tom's books and attended several of his classes. Then along came the \_Tracker\_ list and now the \_Primitive\_Skills\_ list! Will wonders never cease!

Now I would like to start putting into practice some of the skills I have been learning. I would really like to do some of those "walk-about" someone posted about yesterday.

Thanks Dr. André, for setting up and running this list!

Great to be here,

John Wiedenheft  
wiedenheftj@asme.WEB.AOL.COM

-----  
----

Bo Gullledge

Hello,

I have been on the group for a few days and I am overwhelmed by the great quality of information and the great folks that are participating. Many of you will know me from the TRACKERS email list, but for those of you that do not know me, I will introduce myself.

I started on this adventure when I read THE TRACKER, by Tom Brown, Jr. I knew then that if I wanted to learn primitive skills that Tom would be a highly qualified teacher. I first attended a class at the Tracker School in 1984. I took a 4-day Vision Quest that same year personally led by Tom. From that point on I have had a deep commitment to learn, share and preserve these skills.

Just this year while attending the Advanced Scout class at the Tracker School I approached Tom's wife, Deb, about taking over the webmaster responsibilities for the Tracker School and she said OK. So, today, I am finishing my Masters in computer science while pursuing primitive skills on the Internet and in the woods. I am trying, in some small way, to help promote these skills via the Internet.

I am greatly inspired by the sharing spirit in this primitive skills community and I thank you all for your contributions. I am always happy to learn and practice new skills. I am quite busy these days working on my thesis but I am always happy to answer questions if my limited knowledge may be of some help.

As I said before, I have learned so much already from this group that I cannot say how pleased I am! Again, if I may provide some help to anyone let me know.

P.S. I live in Tampa, Florida. If there are any of you close by, let me know.

Best Regards,

Bo Gullledge

-----  
----  
Mark L. Anderson

Hello,

A short intro. I am a project archaeologist involved with cultural resource management studies on Iowa Department of Transportation projects. Besides my interest in arhcaeology and my degrees in Anthropology I have been interested in primitive skills since I was quite young. I grew up in the Duluth, Minnesota area and have had extensive outdoor time throughout northeast and northcentral Minn., northern Wisconsin and the U.P. of Michigan, and central Ontario. Since leaving Minn. for other points I have lived in Oregon, South Dakota, and Indiana prior to moving to Iowa. I have tried to practice the skill I already knew and learn as many new ones as I came across. I am a flintknapper of some 10 years and am branching out into other experimental areas of prehistoric technology, it all helps me understand and analize better the real archaeological stuff. This listserv is wonderful and I am glad to be a part. I'll contirbute as I can and look forward to learning Lots of new stuff about living in the natural world.

To share a quick story....I was doing a flintknapping demonstration at the University of Northern Iowa one afternoon and had checked in with the director of the student union, who was the organizer of the Multicultural Week of which I was a participant. On walking outside to where I was to knap, the director said to me...."So, when the powers goes off for good, our computers all fail, and all of our industrial machinery grinds to a halt, we should come and find you if we want to continue to eat and such, right?" Needless to say I chuckled, agreed with her, and said that fortunately all can learn to knap and survive if the desire and (perhaps more so) the need were there. Thanks for the list Dr. Bourbeau! Mark.

-----  
----  
Tim Rast

Hello!

I'm new to the list, and must say that I am VERY impressed with the quality of the posts and the caliber of the contributors! I'm sure I will learn a lot from everyone, and will try to contribute when I can.

I don't have years of bush experience -- my interest in primitive skills springs from my interest in archaeology and prehistoric hunter-gatherer groups, as well as a steadfast refusal to grow up. I was raised on a farm in southern Alberta and was always banging rocks

together or cutting down mom's caragana hedge to make bows and arrows

(it was the praries -- you do what you can in lieu of real trees :) Now I'm going to school in St. John's, Newfoundland working on my masters.

(Predictive modelling of archaeological site locations on the south coast of Newfoundland using a GIS.)

This list and the skills discussed here are important to me for a number of reasons. Some are personal, but two relate to archaeology and

archaeologists in general. First, the perspective gained by a student of prehistory when he or she makes a stone tool or drills a hole with a bow drill are invaluable. The weights and measures we make on artifacts

can become abstract to the point where it is easy to forget why we are

studying the materials in the first place. I think its essential to have some sort of hands on understanding of the tools and techniques we

study as well as the properties, limits, and potential of the materials being worked. The second point is the fact that these skills are really cool and are one of the most effective means of educating the public about prehistory. Atlatls, stone tools, bow drills and the like are all pretty amazing the first time you see them. Sitting behind glass in a museum they are curiosities and the people who made them can seem very

alien and distant. Its difficult to identify with them and its easy to judge them against our own culture. But when the hammerstone is in your

hand and you begin to understand how these tools were made and used, you

begin to identify with those past peoples on a very human level. Our connection with the past becomes meaningful.

Sorry for rambling on so long -- I do that sometimes.

Regards,

Tim  
t64tr@morgan.ucs.mun.ca

-----  
----  
Bruce Carroll

Greetings!

I am just getting around to my introduction, (I was swamped with working several deer hides and a bear hide before it got really cold up here in New England). I found out about this list from the Tracker email list and signed up a few weeks back when the mad droves of about 60 others also signed up. I have been backpacking/camping for 25+ years, and during this time got interested in primitive skills. I was looking for a way to reduce the load in the backpack so I could enjoy being out more, instead of being a slave to my hi-tech gear. During my hikes, I would use wild edibles for some of my meals, and learned some meager primitive skills after dropping out of boy scouts. Many years have passed since then and I have taken several courses with Tom Brown jr, and signed up for several more in '97, in addition to tracking courses with Paul Rezendes.

I live on several hundred acres of woods, in a geodesic dome I built, that is completely solar powered, and off the grid. I spend most of my free time out and about. Up until last week, I was happily unemployed, but due to things like mortgage, etc, I had to take a short computer contract to get the bills back in order before I can resume my favorite lifestyle of unemployment, playing in the woods and creating music. My camp outs now are mostly practicing to be the "happy wanderer" where I go out for 4 days or so with just the clothes on my back (and front) and a knife and see how far I get. Usually I turn into the dehydrated or starved wanderer:( but have been getting fairly successful in the last few outings where I'm able to get shelter, fire, water and food within the first 2-3 days. Each time out is an incredible teaching! I recently took up knapping and can now get good arrowheads/spear points and knife type items, so at some point I'll drop the knife and see how far I make it then. I teach primitive skills to kids and am in the process of switching my career focus from computers to primitive skills as my firsthand knowledge increases, and now that I can finally afford to not be a "slave" to some large corporation for my daily grub(s).

In Peace,

Bruce Carroll  
Virtual Mountain  
New Hampshire  
Bruce

-----  
----  
Grant Goltz

This post will serve as a partial intro (more later as time permits)...

I live in north-central Minnesota and conduct archaeological and paleoenvironmental research. Much of my time is spent on researching and replicating various technologies used by Native peoples of the region (primarily prior to European contact). My most significant speciality is indigenous ceramics. For the past 15 or so years, I have been researching and replicating these technologies. My goal has been to attempt to replicate the various technologies in as close a manner to that exhibited by the archaeological record as possible, using the same materials as would have been available.

In the process, I have made several hundred vessels of all sizes and styles, and have used many of them for cooking and processing. I can say that these ceramics are amazingly sturdy and functional.

Mark D. Ball

I have just joined the list, and so far it's great.

I am a plastic surgeon, living in Redding, CA. I got to this list because of a hunt that took place this past fall. I shot a bear with my bow and was unable to find him for 24 hours, though he had gone only 40 yds. into a large willow thicket. It became painfully clear to me that I had no business hunting if I could not track what I shot. I happened on the brother of a friend who had taken Tom Brown's standard course here in CA

last Aug.. That lead me to Tom's books, which lead me to the school, which lead me to the web page, which lead me to the Tracker list, which lead me here. This is great!

Mark D Ball  
mball@mercy.org

-----  
---  
Chuck Hudson

Hi all:

I have been subscribed to this list for about a month now and decided that it was time for me to introduce myself.

I am relatively new to the primitive skills thing. In fact I had never heard of any of this until last spring when I became a volunteer at a living history park (Virginia's Explore Park) located just outside of Roanoke, VA.

The park consists of three sections:

The Blue Ridge Settlement, a reconstruction of western VA life in the mid-1800s. This area consists of a farmstead, blacksmith shop, one-room schoolhouse, and a large "bank barn". These are all original buildings which were disassembled at their original sites and the reassembled and restored at the Park. The farmstead grows crop varieties and raises animal breeds which were common during the early-mid 1800s. They also give demonstrarions of various 19th century life skills.

The second area is the "Longhunter's Cabin" this is a reproduction of the cabins which were common in western Virginia during the late 1600s through the mid 1700s. Again, the period costumed staff here give lifeskills demonstrations appropriate for their period.

The third area, and the one where my wife and I both work as volunteers is the native american village. This village is a reconstruction of the lifestyle of the siouan speaking peoples who inhabited the Roanoke Valley before the coming of the europeans.

This village, based on archeological finds, journals of the earliest explorers of the area, and other sources, is being constructed using the tools and methods these people had available to them prior to white contact. Most notably this means that we do not have the luxury of metal tools, nails, etc.

Since working there I have learned to make fire, bark baskets, dogbane cordage, cattail mats and cattail mats. I have learned to select, and prepare saplings for building, build circular and oval domed structures (wigawa) and remove and prepare bark sheets for use as a covering for our buildings.

I have also begun to learn the skills necessary to manufacture stone tools such as celts, knives, scrapers, fleshers, and drawknives.

I look forward to learning much more from the obviously highly experienced members of this list in the coming months.

regards,

Chuck

"Charles E. Hudson"

-----

-----  
-----  
Kelly Harlton

Wow, an impressive line up! (I almost feel inadequate giving my intro)

Wont "clutter" this very busy list.

My name is Kelly Harlton, just a business owner in northern Alberta (Lesser Slave Lake). Done a fair amount of Survival Camping (lucky enough to have hundreds of miles of wilderness on all sides) I've been a Trapper, a Prospector, (these two just for a couple years), I've been snow caving, spelunking, Skied on a glacier, (these last 3 not extensively though), Most recent excursions include 10 days on the Clearwater river in northern Sask. in 95, 10 days on 3 rivers in BC/Alberta (Kananaskis, Kootenay, Red Deer) and Sea Kayaking/camping of the BAJA peninsula Oct 96. (these last 3 trips pretty "cushy" though). So another words, just gotten my whistle wet. Done some Fire making demonstrations for some schools. I Have not taken any formal training like the rest of you, Just all from my Library of 85+ outdoor books. I'm at that point in my life where I've been there done that as far as Workaholic, building a business thing (done OK so far too but there's gotta be more to life). I must confess doing the "demo" for the schools felt good! Is this how You all got your "start"? I am looking for a place to start, maybe I'll book a course from one of the "teachers" on this list (seems most of your have something on the go) Needless to say I will be posting more questions than

answersso please show me lots of patience.

I am 34(male), started getting into "the bush" when I was in grade 6.  
(first solo winter overnigher in grade 7!!)  
Hobbies include;Camping, Back packing, Wilderness and white water  
Canoeing,  
Hunting /Fishing, X-country(back county), Archery.

"Primitive" skills include; Fire by friction, Fire by spark, various  
shelters, Wild edibles, Cordage, and then feeble attempts at almost  
everything else (eg basket making, hide tanning, rock knapping(no flint  
here), slings, pottery, primitive traps, yes all the threads!, hence the  
value of this list to me!) Initial and most Inspiring authors from 10 to  
20  
years ago; Tom Brown (sorry Ron), Bradford Angier, Mors Kochanski,  
and of  
course many more in the following years.

Oops, I broke my promise already  
End of Clutter

Glad to be a part of the Primitive Skills Research Team!  
At Your Service;

Kelly  
"Kelly Harlton"

-----  
-----  
David Weinstock

Hello! I am David Weinstock, in Middlebury, Vermont. The first  
"survival" book I read was Herter's Guide's Manual. I was a Scout  
for many years, back in the days before nylon backpacks and  
Polarfleece. I operate ham radio station W6LR, and prefer  
the now obsolete Morse Code to speech communications. I am a  
freelance commercial writer, and actually spent three years  
as a writer for the L.L. Bean catalog. I came to this group  
from the flintknapping list; as a knapper I'm without skills,  
but with a great wealth of theory. We live in Vermont, in  
sight of the Green Mountains. When my boys are older, we  
plan to resume an active outdoor life--

David Weinstock

-----  
-----  
Ferrell A. Peterson

Hi Everyone!

I've been reading all the input on the various subjects and have  
enjoyed the exchanges.

I have been involved in primitive survival and skills for the last 25+ years. My specialties have friction fires, cordage, atlatls, knapping, rabbit sticks (non-returning boomerangs), and any other skills or projects that have caught my fancy. I recently finished a hickory long bow at Rabbitstick (a primitive skills rendezvous held in Idaho each Fall by Boulder Outdoor Survival School). I've wanted to build a really nice one for years. I've tried to pass these skill on to whom ever would be interested and many of these have been Boy Scouts.

I found the recent exchange concerning two very prominent primitive practitioners very amusing and sad at the same time. Both have contributed greatly to the advancement of primitive skills. That's probably all that should be said. I know Mr. Brown only by his good reputation and that he has helped open the eyes of many to primitive skills and methods. This is wonderful! My eyes were opened by Larry Dean Olsen in 1969. We have been good friends ever since and I appreciate that he has been a mentor to me. This is also wonderful.

What has been the result? Thousands of people have been blessed with a new awareness. That's what's important. Let's drive on folks and share our knowledge.

I have enjoyed the sense of humor connected with body functions and with napalm marshmallows. More than that I enjoy the new perspectives on subjects that are near and dear to me.

Thanks, See you on the net. Ferrell Peterson, aka Fudsy.

When I first read Off Country I thought, "Wow, either this guy has spent years living under every condition imaginable in every place in NA or he is a total fake." I tend to lean toward the fake side. Seems like there is too much info for one man to gather first hand. Thanks for letting me know know what you you think of him.

I agree on the fresh seeds. Maybe this summer I'll do that.

Jeff

Subject: Bushcraft books

Content-Transfer-Encoding: 7bit

Content-Type: text/plain; charset=us-ascii

X-Mozilla-Status: 0001

Adam (in Australia),

You mentioned your bookshelf had a edition in Ron Edwards Bushcraft series. I've learned (here in the U.S.) that Edwards publishing company had filed for bankruptcy and that the excellent series was out of print and unavailable. I can get a copy Edward's "More Bush Leathercraft" through David Morgan a U.S. whipmaker but not the earlier book "Bush Leathercraft" or any of the series books. Myself, I'm looking for the particular volumes dealing with leather braiding and whipmaking. Would you mind giving out your books publication data (year published, ISBN number, publisher - anything that'll help me search through the used booksellers on the net). Also, I've heard a rumour that Ron Edwards publisher had possibly reorganized and may be publishing the series again in Australia. Heard anything on this and anyway of checking with a source at your end? I know 4 or 5 people here in North America that would like to order, not to mention David Morgan's company.

Thanks much,

Chris

Thanks for the scoop. I think I recall the book ISHI (posted previously by others) had a picture of him working a hand drill. If the films show that also, it would be a big help to anyone wanting to learn the technique. One of the things that helped me after a couple of years of failed attempts was watching a quick spot on aboriginal Africans working a hand spindle on a special hosted by (I think) Charles Curalt.

OK, here it is:

#### INTO THE PRIMITIVE

Dale Martin, Paladin Press ISBN 0-87364-530-8  
1989;164 pages. Recommended

>From the Preface

"This book is centered around the concept of having ideas in mind about survival, just in case you actually have to use them at some point. This book is not a 'fight back' book. There are enough of those around. Eighty percent of this book deals with primitive techniques in the following areas: water gathering; food gathering; snaring; trapping; fishing and camping. The 20 percent of this book that does deal with primitive weapons and mantraps is presented to show you how to slow down and agressor and escape, rather than how to be on the offensive."

Chapter 1: Food (pretty good)

Fish gathering techniques

- hollow log trap
- crayfish trap
- bait
- shallow pool trap
- improvised spears and hooks
- fishing pole seine
- cloverleaf fish trap (requires wire)
- fish bomb
- trotlines

Animal-Trapping Techniques

- small snares
- small snare refinements
- box trap
- armadillo trap
- net capture

Chapter 2: Water and Fire (pretty weak)

- solar still
- water purification (does not mention iodine crystals, the best method going)
- lenses, matches, battery and steel wool

-fire drill

Chapter 3: Shelter (very weak)

-tarp shelters

-teepee

Chapter 4: Around Camp

-cooking fires and utensils

-furniture

-toys

Chapter 5: Path Guardians, Alarms, and Weapons (strong chapter; some very nasty stuff)

Overall, a book worth having. I'd say 7.5 on the scale.

Rob

Lots of good line drawings

Howdy,

I just wanted you all to know that Benjamin has an incredible article in the January, February issue of the Backwoodsman Magazine. He covers primitive weapons in a way that would answer most of the questions we've been discussing recently. His illustrations are excellent and very descriptive. If you don't know where to get Backwoodsman you can call and talk to Lynne Richie at 719 783 9028 and get a copy. I know they are out of town for a couple of weeks (getting out of the Colorado snows!) but they'll be back.

Mention my name(if it dosen't pain you too much :>)) or Benjamin's as they're friends of ours.

Happy reading!

and Way to go Benjamin!

I haven't read any of his books for a while. But I do remember that  
"Survival Poaching" was a pretty good book. A lot of information on hunting  
even if you don't want to use the methods (many are illegal).

I just read LIVE OFF THE LAND IN CITY AND COUNTRY by Ragnar Benson. The information is pretty good and seems to be reality based (ie, Benson has done the things he suggests). There are some great ideas for traps (including man traps) but not a very broad range of styles. Benson takes the stance of a survivor rather than a native arts recreationist. That is, he suggests ways of using what you find, even if it is modern. For example, he describes how to use and maintain steel traps. There is a great section on bee hunting, apparently a lost art. Benson has lived through the great depression and seems to know a lot about frugal living in hard times. His attitude seems to be that even harder times are just around the corner. I give the book an 8 on a scale of 1 to 10. I'm not at home right now or I would list the table of contents.

I also have INTO THE PRIMITIVE. I can give a quick review if anyone is interested.

OK, here it is:  
INTO THE PRIMITIVE  
Dale Martin, Paladin Press ISBN 0-87364-530-8  
1989;164 pages. Recommended

>From the Preface

"This book is centered around the concept of having ideas in mind about survival, just in case you actually have to use them at some point. This book is not a 'fight back' book. There are enough of those around. Eighty percent of this book deals with primitive techniques in the following areas: water gathering; food gathering; snaring; trapping; fishing and camping. The 20 percent of this book that does deal with primitive weapons and mantraps is presented to show you how to slow down and agressor and escape, rather than how to be on the offensive."

Chapter 1: Food (pretty good)

Fish gathering techniques

- hollow log trap
- crayfish trap
- bait
- shallow pool trap
- improvised spears and hooks
- fishing pole seine
- cloverleaf fish trap (requires wire)
- fish bomb
- trotlines

Animal-Trapping Techniques

- small snares
- small snare refinements
- box trap
- armadillo trap
- net capture

Chapter 2: Water and Fire (pretty weak)

- solar still
- water purification (does not mention iodine crystals, the best method going)
- lenses, matches, battery and steel wool
- fire drill

Chapter 3: Shelter (very weak)

- tarp shelters
- teepee

Chapter 4: Around Camp

- cooking fires and utensils
- furniture
- toys

Chapter 5: Path Guardians, Alarms, and Weapons (strong chapter; some very nasty stuff)

Overall, a book worth having. I'd say 7.5 on the scale.

Rob

Lots of good line drawings

No, it is not his real name. He lives in town here and his wife works for  
the University of Idaho in town (Moscow). And, no, I am not going to tell  
you his real name.

I have a copy of "Survival Poaching" by Ragnar Benson (I always wanted to  
know, is that his REAL name?) and have tried the legal methods (well not  
so illegal methods, lets just say I kept to my legal limit). This book

has the quick lime in a bottle approach to fishing. that always reminds me about the joke where the old mountain man (hey, I was raised 9 years in West (by God) Virginia) hand the game warden a lit stick of dynamite and asks if he wants to talk or fish. OK, I don't tell it so well.

Anyway, I think that it is a rather good book. A good read, good information, accurate and helpful illustrations, and useful. I like Ragnar's writing style. Best that I can say is that if I lost this copy I would buy another.

Mark: There's a book out on dry scrape brain tanning that I found to be an excellent resource. It's called Blue Mountain Buckskin by Jim Riggs. It Costs \$12.00. Write him at 72501 Hiway 82, Wallowa, OR 97885 The Book is very well written and Jim has a great sense of humor. You'll find it answers a lot of questions. Even ones you haven't thought of yet!

There was a question of how do you get brains. Supposedly, each animal

comes with enough brains to tan its own hide, but friends of mine that do a lot of brain tanning get pork brains out of the meat section at the grocery store ( you might have to hunt a bit. Not all stores may carry it).

Hi Rob. Reading your posts makes me think you have the most nearly complete library of primitive skills books of anyone I know. If you have a readily available list of your books, I would bet that this group would be interested. I know I would.

USDA Food Plants Of The North American Indians

Date:

Thu, 30 Jan 1997 18:33:38 -0900

From:

James Knox

To:

trackers@segun.muskoka.net

Fellow trackers

Thur afternoon

With all this talk of late on plant ID I was wondering if anybody knew about Elias Yanovsky's 1936 USDA misc. publication # 237 titled "Food Plants Of The North American Indians"? I have a copy of this publication. It was given to me long ago by a close friend who was a botanist. He said at the time that Elias (who was not a botanist) realized long ago that the incredible knowledge of medicinal and food properties that the various tribes possessed was quickly vanishing on the reservations from lack of use and poor living conditions (which were causing the people with this knowledge to vanish). He therefore set out to record as much as he could, visiting as many tribes as he could both in the US & Canada. And he did a very good job, for this publication contains 1,112 species belonging to 444 genera of plants distributed among 120 families.

But here is the drawback: to the method of plant ID and classification many of the species quoted in this document have been reclassified for a variety of

reasons: an earlier description was found so another name was honored, a species was later found to be merely a variation of a known species, etc. Therefore I was wondering if anyone knew of a revised version of this wealth of plant knowledge? Has a contemporary botanist ever gone through this publication and revamped it so the older plant classifications have been replaced by present day species? If not somebody should find a botanist who will or an 80 page summary of what knowledge on many types of plants was available back in 1936 will continue to be untapped.

I am not a botanist by any means, in fact in wilderness my plant knowledge is sadly lacking. My forte is animals. But if someone out there wants to work with this publication and can not locate it locally, post my site and I'll see what I can do.

James

Whew! I can see I need to start building bookshelves and squirreling away more book money. Thanks. Have you seen Carla Emery's book,

"An Old Fashioned Recipe Book - The Encyclopedia of Country Living" ?  
9th Edition, 858 pgs. paperback  
\$24.95 / \$33.95 Canadian  
Sasquatch Books  
ISBN 0-912365-95-1

Published by:  
Sasquatch Books  
1008 Western Avenue  
Seattle, WA 98104  
(206) 467-4300

To contact the author, write or call:  
Carla Emery  
PO Box 209  
Kendrick, Idaho 83537  
(208) 289-5575

Started as a 3 holed multicolored mimeo'ed collection of pages with hand drawn illustrations, cardboard covers and wire electrical wire snippets to twist through the holes. My copy's with my sister-in-law. It changed her life from homecoming queen to tipi dwelling wilderness hunting & fishing lodge owner (scratch one point for me). Currently professionally published and finished, it has long been a standard of the Back to The Land bunch and has a large group of dedicated reader/contributors. The basic idea was and still is - a recipe book, but first find and buy the land, prepare the soil, plant and raise the food, harvest, butcher, can, pickle, dry and otherwise put the food by and finally cook it in recipes. Basically a complete treatment of what she was doing to raise a bunch of small children with her husband on a farm in rural Idaho. Raising rabbits, butchering goats, tanning hides, putting together a fruit and nut orchard, filleting fish, pulling calves, raising quail and pheasant, cooking snails, frying snakes...if it's not in here it probably hasn't happened yet. Scald a pig? OK, we'll make the equipment first and then catch that pig! It took off (the book, that is) and she included a School of Country Living, did radio and TV interviews, etc. Raise catfish in a barrel? Extracting oils? Felling trees? Foraging? Sugaring? Trimming hooves? Chopping chickens heads off? I want a wife like this! Really a fascinating woman with an engaging life story and her remarkable book of amassed country living skills that's just boggling in scope. Her kids grew up and moved and her marriage went by the wayside, but her book has taken on a life of it's own and taken a whole lot of people along with it, with world-wide contributors joining her mission. Lots of humor and a

good recipe book! I'd take this one with me if the sky was falling.  
Only fair that you should know of this book, since it will cost me  
dearly to accumulate a portion of your book titles .

Chris

Hello all. i just got in a seed catalog from Native Seeds/SEARCH. Lots  
of uncommon veggie varieties. Run by Native Americans. They also have  
some books for sale and this one sounds like it would be great for us.  
"BUFFALO BIRD WOMAN'S GARDEN" as told to Gilbert Wilson. This remarkable  
Hidatsa Indian woman shared her expert gardening abilities at the  
beginning of the century. She describes the entire years agricultural  
activities in the Northern Midwest in detail, including recipes for  
preparing the food, storage techniques, and implements. 127 pp. paperback

These folks can be contacted at: <http://desert.net/seeds/home.htm>

Adios,

Bob Cox

An astute observation Mark. A quick count shows about 190, not counting the martial arts books or back issues of magazines. It would take a while to list them all but if enough of you are really interested, I will do it. Otherwise, Mark, I will have a list by the time I see you in May.

Rob, PLEASE do send us a list of your books. That's exactly the type of information we like to see being circulated. Perhaps you can start by those you feel are most important. Also, any book reviews by any of our members on books they have which are a little uncommon would be very welcome by many I'm sure.

Also, if anyone has copies of back issues of magazines related to primitive skills you could dispense with at a moderate price, please E-mail me personally, I'm looking for many of them, and so are some of my students.

I would also like to know if there is a used-book market out there somewhere that you are aware of for books on primitive-skills.

Thanks for your help,

PS, regarding books:

"The Tree Indentification Book" by George W.D. Symonds and a companion

volume

on Shrubs are what I bought when I attended the Basic class years ago. They are large format paper bounds, but have lots and lots separate B&W photos of leaves, twigs, bark, flowers, etc, etc.

I've also used the Audobon book on trees quite a bit, it also has good pictures, in color even, of the bark, the leaves and flower and sketches of the overall shape as well as more habitat info than the Identification book.

But it's harder to use it for identification. On the other hand, it'll fit in a pocket.

Here in Missouri, the state puts out a guide for identifying trees in the winter. A lot of it requires measuring things to within a few millimeters and cutting twigs to examine the interior structure.

My wife found "Newcomb's Wildflower Guide" to be about the best for positively identifying something -- unfortunately you have to have a flower present. And nothing on trees. You also have to be willing to count the petals and go through a pretty rigorous classification to find your target -- but it works like a champ once you figure out racemes, spikes, panicles and so forth.

Peterson's has also just come out with a new volume on medicinal plants that seems to be pretty comprehensive.

>From my latest issue of MAPOM News:

New Book: "Wet-Scrape Brain-Tanned Buckskin: A Practical Guide to its Manufacture and Use"

Stephen Edholm and Tamara Wilder, among our favorite and best instructors, are the authors of this new book. We know of nothing else on the subject which is anywhere near as extensive. Over 300 pages with more than 120 illustrations and photographs are included.

Chapters will include History, Skin Structure, Why Make Buckskin, Why Wetscrape and What is Dryscrape, Health Concerns, Tools and Sharpening, Water and Work Area, What Kind of Skin to Tan, Acquiring Hides, Skinning Heads, Brains & So On, Care and Storage of Raw Hides, Scraping Basics, Fleshing, Soaking, Graining, Membraning, Braining, Softening or Breaking, Smoking and Sewing Holes, Troubleshooting Finished Buckskin, Using Buckskin, Buckskin Clothing, Care of Buckskin, Field Methods for Braintanning, Dyeing Buckskin, Braintanning Deer Hides with the Hair On, and Some Other Uses of the Deer. A bibliography and index are included.

You can get a copy at the prepublication price of \$17.95 plus tax (\$1.30 per book). No shipping will be charged on orders received before Nov. 1. Publication is expected before Dec. 1. Order from Paleotechnics, P.O. Box 870, Booneville, CA 95415.

I came across what I consider to be the best Plant Identification book ever printed recently and thought I'd share it with the Group. It is called Weeds of the West and is published by the University of Wyoming Press. The ISBN is 0-941570-13-4. It can be ordered through U of W, PO Box 3313, Laramie, WY 82071-3313 (307)766-2115. This is an incredible guide to plant identification. It contains no information about uses of the plants. It was written to help range managers identify and control their rangeland. However, it has 630 pages with color plates showing the plant in maturity, with close ups of any leave or flower detail that make IDing a breeze. It deals with all plants and grasses (the most extensive grass survey I have ever seen), but does not cover trees. (hence the title WEEDS of the West). It is designated a Western guide, but truly covers North America pretty comprehensively. Absolutely the best ID book out there, bar none! It costs between \$16 and \$30 depending on how many you purchase at a time.

And now for one of my favorite subjects. I will not mention the Peterson or Audubon guides as everyone knows about them.

#### PLANTS

Allan Hall

THE WILD FOOD TRAILGUIDE

All B&W line drawings.

Euell Gibbons

STALKING THE HEALTHFUL HERBS

A classic. Notable for recipes and personal stories.

Edward Knobel

=46FIELD GUIDE TO THE GRASSES AND RUSHES OF THE UNITED STATES

All B&W line drawings. Only about 80 pages.

Arthur Stupka

WILDFLOWERS IN COLOR

Very nice color plates.

Amchem Products Inc.

HAVE A WEED FREE LAWN

Supposed to be a guide to pest weeds so you can kill them with chemicals. About half of them are edible or medicinal. The best control measure is to eat them. They get intimidated. You can often get free booklets from pesticide companies. Check your hardware or garden store.

Ortho Books

CONTROLLING WEEDS

Great color photos and line drawings. \$9.00

The O. M. Scott & Sons Co

SCOTTS GUIDE TO IDENTIFICATION OF DICOT TURF WEEDS

B&W line drawings. Small, sturdy fieldbook with wire spiral binding.

Christopher Nyerges

WILD GREENS AND SALADS

All B&W line drawings. Good recipes

Christopher Nyerges

GUIDE TO WILD FOODS

B&W line drawings. Some B&W photos. Includes medicinal uses.

Thomas K. Squier, ND

LIVING OFF THE LAND

Softbound but typewritten. Has a lot of unique stuff like "Growing your own mushrooms" and "Does herbal medicine work"

Barrie Kavasch

NATIVE HARVESTS. RECIPES AND BOTANICALS OF THE AMERICAN INDIANS

Peter Gail, PhD

-VOLUNTEER VEGETABLE SAMPLER. RECIPES FOR BACKYARD WEEDS

-ON THE TRAIL OF THE YELLOW FLOWERED EARTH NAIL (DANDELION)

-THE GREAT DANDELION COOKBOOK

-VIOLETS IN THE KITCHEN

-DANDELION CELEBRATION

Peter is a friend of mine so I will give him a plug. He has other good books and a newsletter. For those of you who think dandelions are bitter, try Peter's dandelion pizza. Cover a pita bread with sauce, chopped 'lions, and cheese. Nuke in microwave till cheese melts. The acid of the sauce kills all trace of bitterness. Kids love them.

Goosfoot Acres Press

PO Box 18016

Cleveland, OH 44118-0016

(216) 932-2145

U. P. Hendrick

STURTEVANT'S EDIBLE PLANTS OF THE WORLD

All B&W line drawings. 680 pages. More of an academic reference book.

Tom Squier

THE WILD AND FREE COOKBOOK

Giant hillbillie cookbook. Chapter on road kill.

E. Barrie Kavasch

GUIDE TO WILD EDIBLES

Only 60 pages but good color photos.

Eric Soothill, Michael J. Thomas

NATURE'S WILD HARVEST

A gourmet's book. Pretty to look at. B&W line drawings and color photos.

Bradford Angier

=46IELD GUIDE TO EDIBLE WILD PLANTS

A classic. This book is unique in that it has the benefit of detail from line drawings but also the eye appeal of photos because the drawings are in color. Recommended.

Berndt Berglund, Clare E. Bolsby

THE EDIBLE WILD

Jim Meuninck

EDIBLE WILD PLANTS

A student of the great James A. Duke. Very small booklet good for the pack.  
Jim also has videos.

Jim Meuninck

THE BASIC ESSENTIALS OF EDIBLE WILD PLANTS AND USEFUL HERBS

I have an autographed copy. Does that impress you?

James A. Duke PhD

HANDBOOK OF EDIBLE WEEDS

More rigorously scientific than most books but still readable. Recommended

Pamela Forey Cecilia Fitzsimons

AN INSTANT GUIDE TO EDIBLE PLANTS

This book is unique in that it has the benefit of detail from line drawings but also the eye appeal of photos because the drawings are in color. Small, durable hardback for the backpack. Recommended.

Pamela Forey and Ruth Lindsay

AN INSTANT GUIDE TO MEDICINAL PLANTS

Same as above. Recommended.

L. H. Bailey

HOW PLANTS GET THEIR NAMES

A unique book on scientific nomenclature.

=46rances Densmore

HOW INDIANS USE WILD PLANTS FOR FOOD, MEDICINE, AND CRAFTS

Chippewa Indians of Minnesota and Wisconsin. Classic book-looks like it started life as a doctoral dissertation.

Edith Van Allen Murphey

INDIAN USES OF NATIVE PLANTS

Even has a section on venereal diseases. Recommended.

United States Department of Agriculture

COMMON WEEDS OF THE UNITED STATES

B&W line drawings. Good range maps. 600+ pages

Anne C. Hallowell, Barbara G. Hallowell

=46ERN FINDER

B&W line drawings. Very detailed little pocket guide. Recommended

May Watts, Tom Watts

WINTER TREE FINDER

B&W line drawings. Very detailed little pocket guide. Recommended

May Watts

=46LOWER FINDER

B&W line drawings. Very detailed little pocket guide. Recommended.

Alber Wilkinson

THE ENCYCLOPEDIA OF FRUITS, BERRRIES, AND NUTS AND HOW TO GROW THEM

Probably out of print.

Deborah Lee

EXPLORING NATURES UNCULTIVATED GARDEN

Very unique book. Has the only description of signatures and simialars I have seen in this type of book. Some mystical mumbo-jumbo. Recipes

Thomas S. Elias, Peter A. Dykeman

=46FIELD GUIDE TO NORTH AMERICAN EDIBLE WILD PLANTS

Very similar to Petersons guide to edible wild plants. In some ways I like it better. Highly recommended.

Gary Paul Nabhan

GATHERING THE DESERT

A blend of history, scholarship and country yarns.

Ellen Elliot Weatherbee, James Garnett Bruce

EDIBLE WILD PLANTS. A GUIDE TO COLLECTING AND COOKING

Many B&W photos. Recommended.

Karen Shanberg and Stan Tekiela

PLANTWORKS. FIELD GUIDE, RECIPES, ACTIVITIES

A unique approach. Extensive info and activites regarding only 15 common plants. Good for teaching kids. Recommended.

Charles Francis Saunders

EDIBLE AND USEFUL WILD PLANTS

B&W line drawings. Some B&W photos.

John Lust

THE HERB BOOK

600+ page paperback

Mark Pederson

NUTRITIONAL HERBOLOGY

Extensive nutritional profiles on herbs. Chapters on each of the major bodily systems. Highly recommended.

Michael Castleman

THE HEALING HERBS

Unique in its documentation of scientific studies for many herbs. Each description has a "safety factor" section. Recommended.

Richard Mabey

THE NEW AGE HERBALIST

B&W line drawings. Beautiful layout and color photos. Recommended.

Penelope Ody

THE COMPLETE MEDICINAL HERBAL

Stunning photography and layout. Hardcover. Highly recommended.

Verro E. Tyler, PhD

HERBS OF CHOICE

Tyler has authored over 250 scientific and educational publications. The most completely referenced and believable herbal I have seen. Highly recommended.

Mannfried Pahlow

LIVING MEDICINE

Good mix of B&W line drawings and color photos. Recommended.

Joseph E. Meyer

THE HERBALIST

A classic first published in 1918.

Hans Fl=FCck

MEDICINAL PLANTS

Some of the most beautiful colored line drawings I have seen. Recommended.

Michael Moore

MEDICINAL PLANTS OF THE DESERT AND CANYON WEST

Mostly B&W line drawings with a center section of color photos.

Booth Courtenay, James H. Zimmerman

WILDFLOWERS AND WEEDS. A FIELD GUIDE IN FULL COLOR

More of a visual than descriptive guide. Recommended.

Lawrence Newcomb

NEWCOMB'S WILDFLOWER GUIDE

Has a better plant identification system than Petersons. A big help identifying edible and poisonous plants. Good companion to Petersons Guide to Edible Plants. Must have.

Rob Chatburn

OK people. You asked for it. I will be making posts of selected books from my personal library. There will be several categories:

- Survival,
- Camping
- Medicine
- Plants
- Cooking
- Crafts
- Misc (maybe)

Following is the SURVIVAL category. Books are listed by  
Author(s) if applicable  
Title  
Comments

If you need specific info about a particular book (except cost) you can use private E mail unless you think the topic is relevant to the group.

And now.....the books:

Anonymous

The Chumash People, Materials for Teachers and Students  
Published by Santa Barbara Museum of Natural History. Primitive skills of the Native Americans of Santa Barbara, Calafornia

Department of the Army

Survival. Army handbook FM-21-76 1992

If I could have only one general survival book, this would be it. Has great color photographs of plants and animals. Tom Brown helped edit this edition as evident in the shelter section.

Department of Army

Improvised Munitions Handbook TM-210

Simple, field expedient techniques for home brew destruction.

Readers Digest

Back to Basics. How to learn and Enoy Traditional American Skills

A virtual encyclopedia on damn near everything from building to gardening to metalworking to wilderness camping. Emphasis on semi-civilized skills such as the Amish use. Highly recommended.

Dept. of the Airforce

Aircrew Survival AF 64-5

Small, basic paperback suitable for inclusion in survival kits.

Department of the Army

Survival Evasion and Escape. Army Field Manual FM 21-76

Some unique info like an underground fireplace (sometimes called a Dakota hole). Prisoner of war info. All B&W drawings.

Kenn Abaygo

Fugitive. How to Run, Hide, and Survive

Small paperback with military slant. No illustrations.

Bradford Angier

How to Stay Alive in the Woods

A classic. Good practical info but poor illustrations.

Ragnar Benson

Live Off the Land in the City and Country

More practical than primitive. Recommended.

Bart Blankenship

Earth Knack

One of the best for primitive living skills.

Tom Brown Jr, Jon Watkins

The Tracker

Highly readable biography of another famous teacher. Tom's first book.

Tom Brown Jr., William Owen

The Search

Tom's second book and continuing biography.

Tom Brown Jr

The Vision

Tom's continuing biography-starts into the spiritual/mystical.

Tom Brown Jr

The Journey

"A message of hope & harmony for our earth & our spirits. Continuing biography.

Tom Brown Jr

The Quest

"One man's search for peace, insight, and healing in an endangered world."

Continuing biography.

Tom Brown Jr

Grandfather

"At last Tom tells the live story of his greatest spiritual teacher. A man who mastered and shared the skills of survival, who learned from the beauties of nature, and whose quest for inner peace can enlighten us all."

Continuing biography.

Tom Brown Jr

Awakening Spirits

"For the first time, Tom...shares the unique meditation exercises used by (his students)." Continuing biography.

Tom Brown Jr

The Way of the Scout

"America's most acclaimed outdoorsman reveals the secret training methods of the scout by sharpening our powers of observation and unlocking the mysteries of our physical world." Continuing biography.

Tom Brown Jr

Tom Brown's Field Guide to Living with the Earth

Good coverage of long term survival skills. All B&W line drawings.

Tom Brown Jr

Tom Brown's Field Guide to City and Suburban Survival

All B&W line drawings. Not bad but probably the weakest of his field guides.

Tom Brown Jr

Tom Brown's Field Guide to Nature and Survival for Children

The best book geared for kids I have seen. All B&W line drawings.

Tom Brown Jr

Tom Brown's Guide to Wild Edible and Medicinal Plants

The unique thing about this book is that it is mostly personal stories of how Tom has used these plants. Sort of reminiscent of Euell Gibbons. All B&W line drawings.

Tom Brown Jr

Tom Brown's Guide to The Forgotten Wilderness

"Tom shows readers how to open their eyes to the surprising abundance of natural beauty that can be found in the urban and suburban landscapes and backyards, local parks, highway medians, and even windowsill flower boxes." All B&W line drawings.

Tom Brown Jr

Tom Brown's Guide to Wilderness Survival

Tom's first handbook. Excellent coverage of all the important basics of short term survival. Much unique info. All B&W line drawings. Highly recommended.

Tom Brown Jr

Tom Brown's Guide to Nature Observation and Tracking

The unique feature of this book is his detailed description of reading tracks by "pressure releases" or responses of dirt to the forces of movement. I have never seen this described anywhere else. All B&W line drawings. Highly recommended.

Frank C. Craighead, Jr. John J. Craighead

How to Survive on Land and Sea 4th ed

About the same size and scope as the Army handbook but no color photos.

Barry Davies, Phil Beynon

Survival Is a Dying Art

The basics. Nothing really unique.

Thomas Elpel

Field Guide to Primitive Living Skills 3rd ed

Practical skills presented in a writing style that makes you feel you are right there.

J. Wayne Fears

The Complete Book of Outdoor Survival

An Outdoor Life Book. Large hardcover, very professionally laid out. Covers everything. Highly recommended. (I think this guy is famous too)

Jeffrey A. Gottlieb

Teaching Primitive Living Skills/Survival to Children

Small, self published manual. Gives suggested times of activities and appropriate age groups.

W. Ben Hunt

American Indian Survival Skills

Emphasis on art as well as practical tools. Good photos as well as many line drawings.

Ellsworth Jaeger

Wildwood Wisdom

Large paperback (480+ pages). B&W line drawings. Emphasis on "mountain man" type skills.

Richard Jamison, Linda Jamison

Woodsmoke. Collected Writings on Ancient Living Skills

Another famous husband and wife team. They also have videos. Focus mainly on long term craft type skills. Includes unique stuff like fire piston.

Richard Jamison

Primitive Outdoor Skills

Reprints from Woodsmoke Journal. Detailed info about some unique topics.

Richard Jamison

The Best of Woodsmoke. A Manual of Primitive Outdoor Skills

Compiled from Woodsmoke Journal. Much unique material. Recommended.

Chris Janowsky Gretchen, Janowsky

Survival. A Manual That Could Save Your Life A little of everything.

Some unique tips. Mostly B&W line drawings, some photos.

Bjorn Kjellstrom

Be Expert With Map and Compass

A classic. Must have for basic and advanced orienteering.

James McKeever, Jean McKeever

Preparing for Emergencies

Hugh McManners

The Complete Wilderness Training Book

Fantastic color photographs. Very good for introductory text. I just like to look at this book.

John McPherson, Geri McPherson

Naked Into The Wilderness. Primitive Wilderness Living & Survival Skills

Compilation of their earlier pamphlets. Big paperback, many B&W photos.

Single best skills/crafts book I have seen. Highly recommended.

Raymond Mears

The Outdoor Survival Handbook

Nice mix of skills. Simple but effective line drawings.

Christopher Nyerges

Test Your Survival Skills

Unique self test format based on Nyerges' personally tested recommendations. Some reprints of his articles and newspaper articles.

Recommended

Larry Dean Olsen

Outdoor Survival Skills

THE classic survival text. 1990 edition has forward by Robert Redforsd.  
Highly recommended.

Paladin Press  
Never Say Die  
Basic coverage of everything. All B&W line drawings.

Don Paul  
The Green Beret's Compas Course  
Very small paperback with very big info. This is where I first heard of  
telling time with your hand. All B&W line drawings. Recommended

Don Paul  
The Green Beret's Guide to Outdoor Survival  
Small paperback with unique info. Covers firearms. Mostly B&W line drawings  
some photos.

Don Paul  
Great Livin' in Grubby Times.  
Book II of The Green Beret's Guide to Outdoor Survival  
Small paperback with unique info. Covers firearms. Mostly B&W line drawings  
some photos.

Don Paul  
Everybody's Knife Bible. Green Berets' Methods and Knife Mannerisms  
Very unique uses for knives. Plans for custom survival knife. Mostly B&W  
line drawings some photos. Recommended

Bernard Shanks  
Wilderness Survival revised ed.  
Basic coverage, some unique stuff. Good coverage of weather. Strong point  
is very detailed bibliography. All B&W line drawings.

Larry Wells Roger Giles  
You Can Stay Alive  
Small paperback good for survival kits. B&W line drawings and some photos.

Margaret M. Wheat  
Survival Arts of the Primitive Paiutes  
More B&W photos than text. Very good.

Willy Whitefeather  
Willy Whitefeather's Outdoor Survival Handbook for Kids  
Small self published manual. All text and drawings done by hand. Fairly  
good suggestions and it held my kids' attention.

C. Keith Wilbur  
The New England Indians  
An illustrated source book of authentic details about everyday Indian life.  
All B&W drawings.

John Wiseman  
Survive Safely Anywhere. The SAS Survival Manual  
Large size. Very broad scope. Covers all climates. Color drawings of  
plants. One of my favorites. Wiseman also has videos.

John Wiseman

The Urban Survival Handbook  
Unique info I have not seen elsewhere.

Rob Chatburn

Subject: potassium nitrate

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0009

Some details on potassium nitrate manufacture:

#### MATERIALS

-about 3-1/2 gallons of nitrate bearing earth (from sources mentioned in the other postings; also soil containing decayed organic matter, old cellars or farm dirt floors, earth from burial grounds, totally burned whitish wood ash powder)

-fine wood ashes, about 1/2 cup

-bucket, about 5 gallons

-2 pieces finely woven cloth, each slightly larger than bottom of bucket

-shallow pan or dish, at least as large as bottom of bucket

-shallow heat resistant container (ceramic, metal)

-water, 1-3/4 gallons

-awl, knife, screwdriver or other tool for puncturing

-alcohol, about 1 gallon (ethanol or methanol)

-heat source

-paper

-tape

Note; yield can be altered by changing material amounts while keeping proportions the same

PROCEDURE

1. Punch holes in bottom of bucket. Spread piece of cloth over holes inside bucket.
2. Place wood ashes on cloth and spread to make a layer about the thickness of the cloth. Place second piece of cloth on top of ashes.
3. Place dirt in bucket.
4. Place bucket over shallow container. Bucket may be supported on sticks if necessary.
5. Boil water and pour it over earth in bucket a little at a time. Allow water to run through holes in bucket into shallow container. Be sure water goes through ALL of the earth. Allow drained liquid to cool and settle for about 2 hours.
6. Carefully drain off liquid into heat resistant container. Discard any sludge remaining in the bottom of the shallow container.
7. Boil mixture over hot fire for at least 2 hours. Small grains of salt will begin to appear in the solution. Scoop these out as they form, using any type of improvised strainer (eg, paper).
8. When liquid has boiled down to approximately half its original volume, remove from fire and let sit. After half an hour, add an equal volume of alcohol. When mixture is poured through paper, small white crystals will collect on top of it.
9. To purify the potassium nitrate, re-desolve the dry crystals in the smallest possible amount of boiled water. Remove any salt crystals that appear (step 7); pour through an improvised filter made of several pieces of paper and evaporate or gently heat the concentrated solution to dryness.
10. Spread crystals on flat surface and allow to dry. The potassium nitrate crystals are now ready for use.

Excellent info! I don't remember all of those steps. We were probably just making some really polluted stuff. What I do remember is what we could use either a parachute or a pack bag to hold the dirt. We also used a military poncho to catch the fluids and "T" shirt filters (Mine already had crystals growing on them). Once the crystals had formed the ratio for the blackpowder was:

|                 |         |
|-----------------|---------|
| Saltpeter...    | 7 parts |
| Sulfur....      | 5 parts |
| Charcoal Powder | 5 parts |

These measures are by volume, use a measuring cup instead of a scale or balance.

Now we can really go get those marmots!

Benjamin..... can blackpowder be used to skin a turkey?

It was probably woven much like the mats in BUSHCRAFT. It would be easy to cut grasses of a certain length, dry it, and make a poncho type flexible jacket. If woven correctly it should shed most if not all rain, and cut the wind rather well. It would also be natural camouflage.

Hi Rob,

. Of particular interest to me was the report of  
>his grass jacket. Anyone have any idea about how it might have been  
>constructed?

The Tubatlubal made jackets from Juniper bark. Long strips were peeled free from the tree and placed in layers, in a cape like fashion. The top ends, the ends nearest the neck, are held together with a heavy juniper bark rope. The rope is laid out flat, and the ends are pushed into the rope material, wrapped around the rope once, and reinserted. The rest of the cape just hangs free.

I've made several of these and they can be made in a couple of hours. They are quite warm and dry. Rain just runs off. The biggest problem with them is ticks. Since the rope "collar" is next to the skin ticks love to crawl out of the fibers and attack the neck, hair line and pits. Enough bites can lead to what is sometimes called "ascending paralysis" a result of either the neurotoxin used to deaden the pain at the site of the bite or anaphylaxis. My sources argue both.

Just a quick pointer. Soak the Juniper bark you are using for rope. It is much easier to counter twist.

The mummyfied corps of the stone-age hunter, who is lovingly called "Oetzi" (because he was found on a glacier in the Oetztal) was found not very far from where I live (about 2 hours drive). There is much material available about him here in Austria because the local interest, but it's unfortunately all in german, but I'll do a little research about him and the numeros tools found with him (especially his weapons) and post it to the group. If you have any additional questions please contact me, and I'll see what I can do!

Greetings,

I don't have anything recent on the iceman, but I do have a file of articles on him, copies, if you're interested, I could copy you on them. Just send me \$3 to cover mailing and copy costs. I have a friend named James Parker that made a cape like the iceman from raffia. He might could help you on the cape. The problem is getting him to find the time to return a call or mail, but I can give you his address if you like.

X-Mozilla-Status: 0001

Hi

Ron Hood has an excellent writeup on hypothermia, including a body core temp chart and more symptoms.

It's at

<http://www.av.qnet.com/~diogenes/Bookch4.htm>

And I'd suggest looking over his and Karen's page at

<http://www.av.qnet.com/~diogenes/>

There's three more chapters of outdoor survival stuff there. All in all a very good read!

Thanks Ron and Karen

Merv

Subject: Hypothermia (was Re: Myth of the Happy Wanderer)

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

Hypothermia is stalking you!

How are you feeling? What's your name? What time of day is it? Just a couple of questions to establish your level of consciousness. (Hmmm, mumbling, can't seem to talk well, can't seem to concentrate.) Are you cold? Shivering? Got colder and you stopped shivering an hour ago? Here catch this flashlight. Oops, dropped it eh? Can you zip up your coat? No? Time to get warm buddy.

The stage of hypothermia that I've tried to portray above is about as serious as you ever want to see. At this stage, it's still curable.

The next stage, unconsciousness is lethal. In fact if you do find someone in the unconscious stage, don't try to warm them. The ice crystals you release into their blood system (they may be partially frozen) act just like blood clots when they hit the heart and brain. Transport them cold to the emergency room.

Now, the one who's still communicating. This one's body (core) temperature has dropped. So, very slowly, increase the warmth around him. More cloths will probably not help. His core temp is so low that he's not doing well at generating enough heat. If you give him a hot liquid to drink, you may cause a system shock that will initiate a heart attack. Keep the warm stuff close to normal body temp. No hot fires...close. Out of the wind is good. Strip off cloths, pile them under and over the two of you and give the patient body heat is one of the best.

Milder forms can use more clothing, and/or exercise but once the coordination and concentration goes, you'll probably have to give them more heat.

There's a couple more people on this list that should be able to give more info (hint, hint! I think I remember a RN)

I can look up temperature charts for ya'll too if you'd like.

As a caver, I deal with cold quite a bit. As an EMT, I watch the effects closely. There's no sun underground to warm up with. We carry one time use heat packs, some carry emergency blankets, there's usually a balaclava or two along, and at least two trash bags per person (usually stowed above the web in your helmet).

You gotta watch conduction, sit on the trash bags. Watch convection, put something warm especially on your head.

Wind chill isn't usually a problem below ground, but there is the to and from above. The garbage bags strike again!

When we get them back to camp, if they're not too tore up, we save them for the next time. If they're past use for protection, a little bit of duct tape patches them for use as garbage bags.

The last thing to watch out for is persperation. If you sweat, you'll cool. Keep your exertions below the sweat producing level.

Anyow, nuff from me right now. Lets hear from some more folks

Oh, BTW, we might start a thread on Hyperthermia too!

Stay Warm

Merv

Hey Merv;

Actually you have more info on on site treatment of Hypothermia than I do. By the time they get to me in the ICU we are mainly giving them the next best thing to a couple of naked bodies under blankets. We use a combination of warmed I.V. fluids and slow warming with a K-thermia blanket or Bear hugger blown warm air blanket. When I was in the Army we were taught to take their clothes off and put them next to two other people under covers for slow gentle warming if medivac were delayed. At that point you would have little to loose, because they would die anyway if you didn't. If they are awake, keep them awake, offer warmed liquids(note I didn't say hot) and keep them or get them under the cover.

As a side note, I think that's why so many abo peoples in colder areas start a fire and put some kind of tea on the fire before they do anything else, even if it's only hot water.

Signs of Hypothermia

Degrees Body Temperature

Shivering--rapid breathing/pulse 99-96

Skin: possible red

Intense shivering, If conscious, 91-95

can barely speak. Skin: possibly red

Shivering decreases, replaced by strong 86-90

muscular rigidity. Erratic or jerky movements...thinking is dulled, possible amnesia. Skin: Pale

Person irrational, loses contact with 81-85

environment...stuporous state.

Pulse and breathing slow. Skin: Pale

Lose of Consciousness and no response 78-80

to spoken words. Most reflexes cease.

Heartbeat is erratic. Skin: Pale/cyanotic.

In extreme, body parts may be frozen.

People with injuries, chronic illness or the elderly will show effects of cold much sooner. A person laying on the cold ground or other surface is especially prone to rapid heat loss thru transference of cold (conduction)

Always consider the following: air temperature, wind chill, (or water chill) clothing person has on. How long exposed or how active during exposure.

RESPONSIVE PERSON:

If alert, Remove any wet clothing, and keep person dry., Wrap in warm blankets. Keep the person still and handle very gently. Do not allow person to walk and DO NOT massage OR warm legs and arms...A little at a time, reheat body with hot water bottles, warm air, or your own body. Use central rewarming...(middle of body, lateral chest, neck, armpits and groin). DO NOT REWARM QUICKLY. This will circulate stagnated cold blood and cool the central areas of the body and could cause cardiac arrest.

Provide care for shock...elevate feet. If person is ALERT...give warm liquids very very slowly. DO NOT allow person to eat or drink stimulants.

UNRESPONSIVE PERSON:

Severe Hypothermia. Provide passive rewarming. DO NOT try to actively rewarm. Remove from environment GENTLY to prevent farther heat loss, if possible off of any cold surface.

MAKE sure person can breathe..tilt head back slightly to open airway. Wrap person in blankets...use insulating blankets if possible.

REMEMBER: in extreme hypothermia...heart rate can slow to 10 beats a minutes (normal is 60-100) and body will feel very cold to touch. THE PERSON MAY STILL BE ALIVE even if you can barely feel or cannot feel heartbeat. Place fingers on the artery in the neck (carotid) and try to find a pulse for 30-45 seconds. If no pulse...start CPR...if pulse, DO NOT USE CPR. It is possible, in extreme cases of hypothermia, for person not to reach biological death for 30 minutes or more.

> that

> Stalking Wolf gets caught in

>the far north in the winter and comes close to dying.

INTERESTING THAT this is mentioned.

On the way home this evening, I was listening to an NPR segment on HYPOTHERMIA and effects of same, and different kinds of warm-up methods.

The presenter is publishing an article in the Jan. OUTSIDER, Peter Stark.

Might be of real value for some of the skills members to comment on how to survive in cold temps.

Here in the South, this is not usually a problem, cover the head , hands, layer clothing, keep dry, watch windchill, ect.

One thing that was brought out was improper warming of serious cases. Mention was made of 16 Danish fishermen who were taken from the cold Atlantic, given warm-up drinks, ect. and when they went below deck, into warmth, they all dropped dead.

Now, if I could only learn to "freeze" mosquitoes:)

Subject: Profound Hypothermia Treatment

Content-Type: text

Status: U

X-Mozilla-Status: 0001

An earlier posting noted this treatment;

>UNRESPONSIVE PERSON:

>

>Severe Hypothermia. Provide passive rewarming. DO NOT try to actively  
>rewarm. Remove from environment GENTLY to prevent farther heat loss, if  
>possible off of any cold surface.

>MAKE sure person can breathe..tilt head back slightly to open airway.

>Wrap person in blankets...use insulating blankets if possible.

>REMEMBER: in exteme hypothermia...heart rate can slow to 10 beats a  
>minutes (normal is 60-100) and body will feel very cold to touch. THE

>PERSON MAY STILL BE ALIVE even if you can barely feel or cannot feel

>heartbeat. Place fingers on the artery in the neck (carotid) and try to

>find a pulse for 30-45 seconds. If no pulse...start CPR...if pulse, DO

>NOT USE CPR. It is possible, in extreme cases of hypothermia, for person

>not to reach biological death for 30 minutes or more.

IT SHOULD BE NOTED;

Many fatalities from severe hypothermia occur when the victim is moved  
suddenly or warmed suddenly. The best treatment is no treatment in the case  
of an unresponsive person if the paramedics are on the way. A severely  
hpothermic person can go into cardiac arrest pretty easily if they are picked  
up, made to move (even to rolling over) and exert themselves, etc.

the most important thought;

CLEARLY HYPOTHERMIA SHOULD BE AVOIDED, NOT TREATED

never give up...

NO ONE IS COLD AND DEAD UNTIL THEY ARE WARM AND DEAD

The best reference I have seen on the subject is;

"Hypothermia, Fostbite and Cold Injuries"

Hey Doc!

>Oh, this is TOO personal. Please keep it private Doc. You aren't going  
>to use one of those rubber gloves they been talking about, huh Doc?

No gloves for you Andre'..... No sireeeee. Just my COLD hands groping your  
bottom.....

Kinda reminds me of the two fellas walking through a field. They spot a  
sheep with it's head caught in some barbwire. The one fella turns to the  
other, a brownie and says. "See that sheep, now we're gonna have some fun!"  
He walks up to the sheep, drops his pants and..... shortly, he pulls up  
his pants, smiles and says "Now it's your turn." The brownie looks at the  
sheep, drops his pants, and sticks his head in the fence.....

BTW. The best technique for clingers that I know. Eat two pounds of beans,  
six ounces of spinach, two eggs and a chili dog. Wait two hours. When the  
urge hits, back up to the fire and let 'er rip. The flames will cauterize  
the resulting wound. There will be no hair, no clingers and no little field  
monkeys dropping from that cheeky speaker for some time.

Yer's

Ron

P.S. You can post this if you want..... Perhaps some would find it amusing.

Subject: Re: Passing Gas

References:

Content-Transfer-Encoding: 7bit

Content-Type: text/plain; charset=us-ascii

Status: U

X-Mozilla-Status: 0019

Anyone know where I can get a copy of Benjamin Franklin's "Fart Proudly"?

BTW, talk about your primitive firestarters. Saw my Red-Neck (you might be a Red-Neck, if...) brother-in-law lean over after a family dinner, pull out a Bic lighter and announced, "Hark!" He let go and lit the flame and set his polyester pants on fire as the gas ignited in a big ball of flame diffusing through the weave of his clothing. Falling to the ground under the table to our amused and amazed view, he slapped at his butt frantically for seconds until the orange glow died. Fused the pants to his rear end and legs. Then he went out to sit in the snow and drink tequila.

Oh yeah, you might like this. Last summer I took my family on a lakeside camping trip. We had taken a bag of marshmallows for our 9 yr old son to roast around the campfire. We stripped the bark from some green sticks and loading up a couple I proceeded to transform them into perfectly browned beauties for my wife and son. Whoops! They caught on fire, so I quickly pulled them out on their little whippy stick to huff and puff on them. Molten liquid marshmallow napalm shot out of the side of the burning devils, catching fire as it flew in a stream toward my head. Instantly conforming to the contours of my face the marshmallow fuel flamed up my face towards my hair. Time slowed waaaayyy down as I started slapping my own face, slowly at first, then furiously as it appeared to have absolutely no effect. My family's mouths started

dropping open, slow as opening doors on a barn - their eyes began slow motion opening wide - SWOCK! - looked like two pair of twin umbrella's opening. I could see everything with bright clarity, as my animated self noted the flames climbing my head, millimeter by millimeter, like the frame-by-frame video of an explosion. It dawned on me that my hair was going to combust hair-by-hair next. Slapping my head with blurring speed (as seen by my loved ones) I was just about to bury my head in the ground and roll around at their feet when the fuel unexpectedly burned itself out. Standing there charred, smoking and looking like I'd just been struck by lightning (but first the dancing Wild Man Floor Show! -- where "he moves surprisingly fast for a fat man"). By then their mouths were just about fully gaping, as I shakily patted my head ('just a little bit slower now') feeling for my features. Unexpectedly finding I had glasses, I pulled them off to see they were covered in white goo. They must have saved my eyes. My nose and parts thereabout were another story, as I walked through the next couple of weeks with my constantly hurting pinkly burned 'above the shoulder' and deflated ego area. I started drinking and didn't give a good God damn who saw. Even the hangovers helped. People came to view me like a 'Shrine' and actually fell down laughing at my feet, pointing up at me with tears running down their eyes, convulsed as they were with mirth. One guy wrote me on the internet to thank me for my humiliating object lesson. He'd been feeling depressed and stressed, but that passed like a cloud when he saw what an asshole I was. Now in my bug-out bag sits a little bag of emergency marshmallow firestarters...and a bigger first aid kit.

Believing he needs a beer,

Chris

Subject: Shrinking heads, here's a way?

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0009

>So am I. It might be fun to try this with an animal head. I can see it now,  
>world's smallest elk trophy.... ;-)

>

>Bill B.

OK, OK.....

I watched this..... in the Mato Grosso.It may work with an elk head. It does work with dog (No, I didn't do it to the dog! Dog's are too loyal)

Part the hair on the back of the skull to expose the scalp. Carefully cut a line from the base of the neck to the hairline above the forehead.

Pull the skin away from the skull. Put your fingers between the skull and skin to separate the skin of the face from the facial bones. When you encounter an opening, Eyes, nose mouth, follow the skin into the opening and cut inside the hole to separate the tissue from the skin.

Break the nose at the union between cartilage (sp?) and the bone with a blunt tool like a stick.

Pull the face off.

Turn the skin inside out and scrape away the majority of the fat and muscle left on the skin. Be careful not to puncture the skin. A stone scraper is good. Turn the skin back inside right.

Sew the lips,eyes, nose and mouth shut. Close the opening in the back of the head.

Heat a big bucket of sand (about 100 pounds) 90% sand 5% wood ash 5% salt until the sand is too hot to handle. Do not burn the sand.

Partially fill the skin with the sand. Shake the skin to move the sand around inside the skin. This will take some doing but it is very important. The sand will begin to dry the skin and the skin will begin to shrink. When the sand cools, pour it out and refill, do it again, and again, and again until the head is much smaller. This will take many hours, even days. If you need to rest, hang the head by the hair, in smoke from the fire. You will need to plug the neck if you do this. Never overfill the head. That will stretch the skin, not what you want.

When the head is the size you want, it will feel like a leathery orange, and it won't smell. Pour out the sand and fill with dry grasses. Mold to shape. Repeat the sand routine if it starts to stink.

Peace

Ron Hood

I never thought my first contribution would be instructions for shrinking heads...

The following link describes the method for shrinking heads practiced by the Jivaro tribe of Bolivia. Further investigation will be required to identify the specific herbs to which the article refers. I will leave that to other more interested members. I think I'll pass up the opportunity to acquire this particular primitive skill.

<http://www.museumpress.com/exhibit/jivaro1.html>

(that's a numeric "one" following "jivaro")

Merv, I guess pinching steam is more involved than the simple process of elimination. I've now learned that my dog is a potential "ass-ett", that soaking the cob is an important prelude to that final stroke and when a grogan storms the doors, your anal art should not be decorated with a white butterfly. Fascinating.

To continue the train. In the Sierra we discovered that the steamer will be memorialized, something like a mummified Egyptian brown snake, if it is punched into the earth at above 8,000 feet. Food slag dropped into a hole is not digested by the butt log munching organisms normally associated with decomposition. We've learned this terrible truth as well as the axiom "One man's camp is another man's toilet" the hard way. After having had digital contact with the extraordinarily aromatic contents of another person's colon, I've resolved to avoid digging with my hands.

We've learned through experience that a brown steamer is best vented into a crack between rocks, to a resting spot on top of the ground. It will lay there unmolested for a few days and then the combined efforts of sun, cold, air and rain will erode your brown joy. Within a month there will be no sign. If we avoid corn cobs, bundled hay, cedar cones and other smudging instruments, we will leave no sign whatsoever. Which leaves us with an interesting thought. "How can we drop those little Saddamsís with the least possible damage to our skin?" The answer I think may come with the single cheek lift.

Long ago I had a spiritual revelation. As I lay in a mortar crater with my rifle, half way through a three hour firefight, the spirit rose at groganís door. In that moment I realized that some things are far more important than the abstract notion that I could be killed. I KNEW that a turd would emerge unbidden into a world filled with the acrid odor of rifle fire. Not only that, it would be in my pants.

They say that there are no atheists in a foxhole, itís true. I asked God for guidance. (God DOES have a sense of humorÖ.. why else would he program the body to pinch steam during a life threatening event?)

In a moment I had the revelation. My spirit guide "knuckles" told me to "DropíemÖ.Lift itÖPinch with energy" I did. After lifting one cheek, and pushing HARD, an aromatic missile flew from my body at a speed that would have cracked a windshieldÖ. And landed six inches from me WHILE I LAY ON MY SIDE! Other than having a new companion in my mortar hole, things turned out fine. I did not sleep there that night.

Since that singular experience Iíve quizzed my spirit guide for guidance and Iíve had a learningÖÖ

While perched atop that sundered rock  
waiting for that turd to drop,  
lift your cheek with your right hand  
and on the ground it will land.

Nary a mark will it leave  
and only the air will it cleave.

(Iím waiting for the rest of the lesson)

Ron, I'd imagine that chocolate butt kisses in the snow could be a problem too. I think your alignment crack to crack with rock might be the best idea. That way the steamer dood wont last much past the thaw, if that.

Chris, there's thimbleberries down to the southern Sierra. I've seen (and eaten) thimbleberries in Mountain Home State Forest. That's due west of Sequoia National Park and about 7-8000 feet altitude.

Take Care  
Merv

Oh, enlightened one. Perhaps you will one day offer a "Spirit Krapping"  
course and will tell us that once you master Spirit Krapping you will  
not have to actually physically krap anymore.

Here is a way to tie several threads together. How about a sling with a

nice soft pouch that you can also use to wipe with, and while you are at it, hurl the fresh Steamer as far away as possible, preferably landing it between some very large rocks. This way you handle the delicate job of wiping, and sanitation at the same time. In fact, you could wear the thing and save your self the trouble of having to drop ypur pants. Just deficate, and throw! You can hunt with this sling in the traditional fashion, of course, and descenting won't be a problem because you and your rock projectile are going to smell like crap (which is pretty much how I throw with one). You should definately put one of these multi-purpose babies in your survival kit. And as an added bonus, you can practice by hurling rocks at all your pottery shards and cracked pots! Is this great or what? Talk about conservation of effort! Thanks to all for all the great ideas. Are we not geniusses? or is it geniasses? Geniuses? Whatever. Keep those cards and letters coming.

Kevin!

Brilliant! The butt sling! Innovation is the corner stone of survival. As I

see it, it could even be used in primitive warfare re-enactments. A line of hairy folks aligned in ranks flinging grogans 100 meters at their fleeing enemies.

A contest for speed, the dump-wipe and sling, would be very popular among the "stoners" and "heads".

Environmentally it is possible that the passage of a brown steamer, at high speed, might ablate enough material that it could replace the ozone layer with the grogone layer. I'm fairly certain that the layer could not be penetrated by the Ultraviolet that causes so much trouble.

In fact, as the grogone layer settles to earth in successive waves one might expect that the vegetation would receive a much needed nutritional boost. Eventually this could result in a revitalization of our sorry planet.

I'm stunned. You are a genius. I sit at your feet.

Ron

I guess that I owe someone an apology. I received an Email letter from some courageous soul (whose return address is "Jesus Rules@Angry.God). I tried to send a message to (.God) but Iím afraid there is no .God. hmmmmmmÖ.

Anyway, this person objected to my use of the term "turd" when referring to a feces or scat. OkÖ.. The intent of my language is to communicate information and ideas in a way that is understandable to the largest number of persons. I believe a "turd" is better known than a "scat", so I chose that word.

However, in deference to the sensitive nature of my brave critic I will herewith make the following changes whenever the word "turd" is required. I will call a turd either "a brown steamer" if it is very fresh. A "steamer" if it is reasonably new. A "Grogan" if it is largeÖ.. and "Old steamer" if it may contain materials for making Potassium Nitrate (or ammonium nitrate). (If you agree, oh fearless one, you need only write me another of your wonderful letters.)

I hope that my complainer is aware that Jesus Christ was also a man. As such he was most likely to have pinched a steamer or two in his lifetime (Now that youíve got me thinking, I wonder what kind of fire accelerant THOSE would have madeÖ. ).

If he did not, I understand the "Angry God" notion more completely.

Peace,

Ron Hood

>I donít like the way you yused the t--- word. Jesus Christ dide for our sins and he

>did not want us to use prfanity. The right way to talk about that subject

>if you must talk about it is you use the appropriate word, scat. Or fece.

Dont you ever use that >word again or the Lord will smite you in his terrible wrath.

>God save you because he knows where you are.

Sorry to take up more bandwidth with this subject, but someone out there obviously does not understand that God has a sense of humor other wise he wouldn't have let cousins to the chimp that merely walked upright, have dominion of his creation. Since he did, and taught one of the chimps to use a computer I must accept this as proof that God has a sense of humor. He also humbles man by making him excrete turds (excuse me brown steamers) as part of his existance. AS THE GOOD BOOK SAYS JUDGE NOT LEST YE BE JUDGED So if God is angry he will probably waste the unchristlike but very christian person that sent that post to our brother in primitive sciences. Perhaps you never took a dump in the outdoors, or had to clean fecal matter from your brother/sister man. If you had then perhaps you would have more appreciation for a simple harmless word such as turd. There are worse words, like cowardess. It is a matter of cowardess to not leave a proper

e-mail address for a return message.

In the interests of clarity, I find myself needing to ask a question to clarify the intent of this terminology. Given that they are rare, it is known, however, that they do exist. Therefore, I need to know the proper terminology for paleo-turds. That is, which is more proper, to refer to Juraissic, Pleistocene, etc. turds as very, very, very, very, very, very old steamers or as Stanley Steamers?

>Juraissic, Pleistocene, etc. turds as very, very, very, very, very, very  
>old steamers or as Stanley Steamers?

Good question! I was under the impression that very large, petrified fecal art, is called a "groganoid". I understand that they make a fine spear point as they have conchoidal fractures that occur along the parallel inclusions (i.e. hair etc.) naturally occuring in the deposits. Any Ideas?

Interesting you should mention this. Airborne pungi stakes? Hmmmmmm. Yech! Still, I think it would be difficult to keep a fine point on them, but it should be easy to track where they went. Also, if you did do this, I have a sneaking feeling that the first use for this spear would be to fend off the angry archaeologists!

My grandfather was a rockhound, and taught me to spit on a rock and rub a bit to see what it'd look like polished. I got lazy and just licked them. He broke me of the habit of licking rocks by handing me a piece of coprolite, letting me test it for polish (by licking of course) then telling me what it was. I swear, that stuff had a petrified stink with it when I knew what I'd licked!

Also, while on coprolite, did you all know that dinosaurs were very advanced poopers? Yes, indeed. Their turds are even tapered at the end, just like ours. Yep, that way their assholes wouldn't slam shut. Can you imagine a herd of bracheosauri pinching squared off steamers? What a noise! They'd never hear the tyrannasaurus rex stomping down the trail!

Hmmm, Maybe tapered turds are a survival trait! Hmmmm.

I need to go cogitate

Merv

In a message dated 97-01-16 23:21:54 EST, you write:

<< If rock is wet, it's raining  
If rock is dry, it's not.  
If rock has a shadow, it's sunny  
If rock sticks to fingers, it's freezing

Is this the one you mean?

>>

That would be the rock I meant.

However, there are a couple more features.....

If rock is moving, it's windy.

If rock has snow on it it's snowing, or has snowed.

Here's a new one: If rock is vibrating, LOOK OUT!

You may be near an active earthquake fault!

But seriously, this weather rock is kind of a silly thread.

We should really be discussing what materials and  
methods will be used for the tripod we lash together  
to support the weather rock.....

That's why nature is such a great teacher, and sometimes not a forgiving one. As a boyscout we decided to show how salty we could be, by baking a cake in a dutch oven with coals. We didn't have a lid, and we remembered a method where we covered the batter with grape leaves and put coals on top of the leaves. Well we didn't have any grape leaves either. There was one tree that had big leaves that looked like it would work though so we used them. Well we managed about one bite a piece, and didn't swallow that one. That cake was so full of tannin it was awful. Never used oak leaves after that though. ;-)

Our troop frequently does "Hobo Dinners" or "Tin-Dins". You put un-cooked meat (chicken, hamburger, etc) in the center of about 1 ft.

sq. of HEAVY aluminum foil (double if not heavy duty). Add vegetables or other stuff (imagination is great - I've used apples/oranges w/pre-cooked ham) cut up into 1" pieces, season to taste, and seal. When sealing, fold two edges up and together and fold at least twice. Then fold the other two edges at least twice toward the center. This should result in a square pouch that is completely sealed. Throw on coals, turn over after about 15-20 min and cook another 5 or so. These can be prepared ahead of time, frozen, and used in place of ice to keep a drink cool. Pre-cook your meat for longer un-thawed life. Your troop could open up their pouch to add meat if earned. Our boys like the fact of no clean up after the meal.

there are a couple of routes you can take.

1 wrap a small roast or two separately in 3 or 4 layers of heavy duty tin foil.  
wire them close to the exhaust manifolds in you car.

if going a ways to your camp-site these would cook quite well.

2 you could find or bring some clay with you and make a large pot and fire it  
at camp. presto a pot.

3 you can get a brain-tanned hide and suspend it over your fire with water  
and vittles.

4 set a rain-tanned hide with water and vittles beside a fire. heat non-river  
rocks in fire. heat rocks rince in water then put in hise till heat dissipates.  
then replace with new rocks till food is done.

in both 3 and 4. 4 sturdy posts should be set up to create a pocket in the  
hide.

hope this helps, let me know ok. personally i would try one or two of  
the methods in my back yard first and get some knowledge about how to  
fire clay without a kiln.

Howard, have you tried any of these things that you have made note of?

There is a lot more to pottery firing than you mentioned. You might want to access the pottery thread for some really great info that has been shared on this subject.

> and vittles.

A fresh rawhide will work this way but I don't recommend a braintanned hide. For one thing why go through all the trouble of the entire tanning process if your just going to cook in it. A fresh rawhide suspended and formed with an opening made from a willow hoop can actually be suspended over hot coals by a tripod and cooked in. It drips like crazy, though. If you hot rock cook in it it hardly drips at all though. It can also be just used to line a hole in the ground if you are going to hot rock cook in it.

> 4 set a rain-tanned hide with water and vittles beside a fire. heat non-river

I don't know what you mean by "rain-tanned hide".

Finally, did I miss something I see no other thread to this note, what was it in reference to in the first place?

Here are a few things I have used for cooking methods. I'll just e-mail  
you my text-only version of my article that is presently in Wilderness  
Way magazine if you'd like to check it out. Outdoor cooking is  
definitely a specialty for me. See article following sig.

WILDERNESS COOKING METHODS

By Benjamin Pressley

Copyright Benjamin Pressley 1997

Cooking in the wilderness...what visions of rapture it brings to  
mind. Some of my richest experiences have been enjoying a meal cooked

over an 'open fire' stretched out by some mountain stream. Food just seems to taste better cooked and eaten outdoors, doesn't it?

There are some pretty decent light-weight systems on the market for cooking on the trail, if you have the money and you are willing to carry all that stuff. My quest for many years now, though, has been to simplify; Re-examine my philosophies and gear for lightweight travel and efficiency. In this process I have discovered or re-discovered some cooking methods that have been used by explorers and prehistoric people of the past for thousands of years that work just great and certainly lighten the load on my aching back!

These cooking methods are also a valuable survival skill. Each year many unprepared, unsuspecting, outdoor loving people are thrust into a survival situation with no modern gear. The number one killer, statistically, of a person thrown into this situation, is lack of knowledge. They get paranoid. They think only of what they don't have instead of what they do have and make all the wrong choices. Every person that enjoys the outdoors should take at least a basic survival skills course and a first aid course.

There are many methods of cooking in the wilderness, without aid of modern gear. Some require production of a simple tool or container and some use no kind of utensil at all, utilizing only the fire and the coals it produces. Cooking in the wilderness, even in a survival situation, without the aid of modern gear, can be accomplished very effectively if one will only use their head, look around them and use whatever materials they have on hand to produce whatever cooking implements are needed for the given task. After all, every pot, pan and spoon we are familiar with was manufactured from some raw material at one time or another.

In almost all cases, whatever you are cooking requires the coals of the fire and not the fire itself, unless you are toasting, browning or reflecting the fire's heat. Many people make the mistake of trying to cook over an open flame, which in most cases burns the outside of what they are cooking, leaving the inside uncooked. The reason for this is flames are hotter than coals and more inconsistent in heat distribution. Open flames register temperatures that are jumping anywhere in temperature from 200 degrees F to 1000+ degrees F constantly.

Furthermore, all woods do not burn at the same rate. Hardwoods burn

slower and hotter than soft woods. There is also a difference in the way evergreen trees burn and deciduous trees burn. Evergreen trees have a resin or 'gum' that causes 'hot spots' in the fire. Does this mean you should only use one kind of wood to cook? No, it just means that you need to be aware of the differences between woods. The chart included in the sidebar entitled Qualities of Various Woods will help you choose the right wood for the task at hand. Some of the methods described below require food have direct contact with the wood you are cooking on. Especially in cases like these you want to avoid evergreen coals because of the taste they will taint the food with. Whatever you are cooking you need to have enough coals to complete the cooking. For this reason it is a good idea to keep a fire going producing coals while you use another area of your fire ring or a separate fire ring or pit to cook in where you may constantly transfer coals as needed, thereby, keeping an adequate supply of hot coals on hand. You may avoid 'fishing' out coals and scorching your skin in the process by carefully 'flipping' the fire. To accomplish this you will need a large enough fire ring with fire built at one end. When there is a sufficient supply of coals burned down then carefully move the fire and any wood that is still burning to the other side of your fire rings, thus leaving a bed of coals behind. Add additional kindling or fuel if needed to stoke the fire up again. The fire can be 'flipped' as many times as needed back and forth within the fire ring. When done carefully with long sticks to aid in 'flipping' the fire, this is often safer than trying to 'fish' out coals from under a burning fire. A fire will also serve you better, if you plan the type of fire arrangement you will need in advance for the job you will need it to do. Never build a fire larger than you need it to be.

It is a good idea to know how hot the fire or coals are that you wish to cook on. Lynn Hopkins, an expert dutch oven cook, came up with this method for determining the temperature of the fire or coals. Try holding your hand about three inches above the spot you intend on cooking over. Count how long it takes for you to move your hand because it is too hot, in one second counts. Now, look at the table below to find the approximate temperature of the fire or coals based on your count:

COUNTS

HEAT

TEMPERATURE

|                         |          |                   |
|-------------------------|----------|-------------------|
| 6 to 8<br>(120-175C)    | Slow     | 250-350 Degrees F |
| 4 to 5<br>(175-200C)    | Moderate | 350-400 Degrees F |
| 2 to 3<br>(200-230C)    | Hot      | 400-450 Degrees F |
| 1 or Less<br>(230-260C) | Very Hot | 450-500 Degrees F |

When using any cooking method keep normal cooking times in mind and the temperatures you are working with based on the chart above. You should also check the item you are cooking frequently and turn it regularly, except in the cases mentioned below that require no checking. Following the guidelines included and trying these methods out and getting a 'feel' for them is the best way to be successful at them.

Let's look at a few cooking methods:

#### FLAT STONE COOKING

A flat stone either pre-heated in the fire or placed over two other stones and hot coals raked beneath it will make a fine griddle for cooking cakes, eggs, meat or just about any item you would normally cook on a griddle. Soapstone is a particularly good choice for it retains heat for a long period of time and heats evenly throughout. However, I have cooked on a 'griddle' made of granite many times. I actually was challenged on this once and accepted the invitation to a contest between my rock and the challenger's frying pan. We were given the same amount of coals from the same fire. We each cooked pancakes from the same batter. I was still cooking pancakes long after the challenger's frying pan and coals were cool!

#### ASH COOKING

This is kind of a misnomer, for to cook using this method you place items to be cooked right on the bed of coals, not a layer of ash. Many foods may be cooked by placing them right on top of the hot coals themselves. If you use hardwood coals you will have very little to no ash to stick to your food. A little ash will not hurt you anyway. A dough prepared and flattened into cakes or rolled into balls and placed

directly on the coals will cook just fine. When the outside is thoroughly browned just remove from the coals and break open and eat the bread from inside or rake off the ashes and eat whole. The outside is usually too burned to eat by the time the inside is done, but the inside is very tasty. Steaks may be laid directly on the coals and turned frequently. Laying meat directly on the coals really sears and seals the meat's natural juices in and makes the juiciest steak you ever ate! Tubers, such as potatoes can be cooked this way. You should bury them in the coals. You can poke at them to see if they are tender. Don't let the hard feel of the outer layer deceive you, though. The longer they stay in the coals the thicker this outer layer will get, as it burns. Corn on the cob, open husked, soaked and placed back in the husk and laid on the coals steams corn very well. Turn frequently.

#### SPIT COOKING

A spit is a green stick used to skewer the items you wish cooked and then either held over the coals or supported by two forked sticks or allowed to dangle over the coals by jamming the other end under a stone or stuck into the ground. This method can be used like a shishkabob for chunks of meat and vegetables. Dough may be formed into a snake and spiraled around a stick and baked over the heat of the coals or near an open flame. Be sure to turn frequently, you only want it to brown. Eggs may be cooked by making a miniature arrangement of two forked sticks, carefully pecking a tiny hole in each end of the egg and skewering the egg and placing it across the two forked sticks near the fire. The holes give you a means of skewering the egg and also allow steam to escape to keep the egg from exploding.

When cooking a small animal like a duck, squirrel or rabbit the problem is often encountered of the meat not turning with the stick, as you turn it. This problem can be solved by drilling two holes in the middle of the stick you are using to skewer with. Whittle two smaller sticks that will fit through the diameter of the holes you just drilled snugly, pointing them on one end. Now, skewer the beast as before and pierce the body through with the two smaller sticks, through the drilled holes and through the other side of the meat you are cooking. Now, it will turn when you turn the skewer, rather like a rotisserie. You may also wish to bind up the meat with some sort of string to keep legs and such from dangling and falling into the fire as they cook.

## DANGLING

A small animal such as described above may also be cooked by wrapping the body with string, securing all dangling parts and then allowing enough length to dangle it near the fire with a tripod or 'dingle' stick. This allows the meat to turn and cook evenly by giving it an occasional whirl. Just don't dangle close enough to the fire for it to scorch the meat and/or burn the string in two. It is a good idea to use a reflector in conjunction with dangling. You may also wish to catch the drippings in a container, if you have one, for cooking and flavoring other foods, such as gravy.

## REFLECTOR COOKING

A reflector may be as simple as several short logs stacked on one another to the height of two to three feet and staked on each side to keep from tumbling down or it could be constructed to have three sides thus utilizing more heat. Slanting your reflector so it is farther out at the top than the bottom is also more efficient than a wall perpendicular to the ground. The reflector should be placed behind the item being cooked so the item being cooked is between the reflector and the fire, reflecting the heat of the fire and cooking the meat thoroughly. The reflector can be used in combination with many of the cooking methods described here, not to mention the warmth it can provide you by situating your shelter so you are between the shelter and the fire with the reflector to the other side of the fire reflecting the heat back to you.

## CLAY COOKING

Cooking meat by covering it with clay and baking it in the coals has the effect of a clay oven and steams the meat until tender and juicy in its own juices. To use this method acquire some good sticky clay or mud, and smear it over the entire item you are cooking. Punch a hole with a small stick through the clay to the meat to allow a place for steam to escape. Place it near the fire to allow the clay to harden, then checking to make sure your steam hole is still clear, place it in the hot coals and cover it with more coals, being careful not to cover the steam hole, otherwise it can explode, then, cook until done. Fresh fish or fowl, cooks up particularly well using this method and you need not remove feathers or scales as these will pull off as you remove the clay. The entrails cook into a small ball in the body cavity that is easily

raked out after cooking and does not taint the flavor of the meat. In the case of any other animal, it should be eviscerated and skinned and covered with yucca or grape leaves, even brown paper, to prevent any grit from staying with the meat. You may also wish to place herbs and spices in the body cavity before covering it with leaves and clay.

#### STEAM PIT

The steam pit is a pit dug large enough to hold the items being cooked. It is then lined with stones and a fire is built in the pit heating the rocks around it. The fire and coals are then removed or some coals may remain provided they are covered with a layer of ash and wet grasses. Pile these wet grasses and perhaps some wild onions on the bottom of the pit and then place the meat and tubers or whatever you are cooking on the top of the grass and then pile more grasses over this. Grasses are not poisonous. The only caution here is in the case of grass seed. Grass seed is edible but only if they are not covered with a dark colored fungus known as ergot. Ergot is a toxic fungus. You may add some water, but, not enough to cool the rocks down, just enough to cause steam. Then, seal the opening of the pit with a flat rock and seal this over with dirt. This type of cooking is very good because it need not be constantly attended, in fact, the pit should not be opened until the food is done. You need not worry about food over cooking in the steam pit for it is cooling down as it is cooking. You can place items in it to cook and come back 6-8 hours later and have a hot meal waiting for you and since it is buried you need not worry about animals eating it before you. It is also very nutritious, for it steams in the flavor and vitamins.

#### HOT ROCK COOKING

For hot rock cooking you will need a container of some sort. A bowl may be produced by burn and scrape methods (See sidebar: Burn and Scrape Bowls) or a tightly woven basket that will hold water or a fresh rawhide staked to the sides of a pit or suspended by a tripod (rawhide may be suspended over a fire by a tripod for boiling but it does draw up and leak terribly, using the hot rock method, it does not hardly leak at all.) Liquid is then placed in the container for stew or for purifying and rocks are heated in the fire, several, about large egg size or a little larger. Be careful heating rocks. All rocks may explode when heated. Those found in the water should be particularly avoided as these

may hold water within them exploding when heated. There are many simple methods of producing thongs. The one I like best was shown to me by Jeff Gottlieb. You simply bind a green limb of suitable length at one end. You then split the limb from the other end up to your binding. A small stick may then be placed to wedge the thongs open and provide a fulcrum for the thongs to bend against like a spring when being used. When the rocks are hot place them one at a time in the water, with the thongs, you may wish to brush them off a little, to keep ashes from getting in the stew. The heat in the rock will be imparted to the water, gradually causing it to boil. You then remove the rocks from the liquid and place them back in another part of the fire, so you don't get them mixed up, to heat again. You continue doing this for the length and temperature of the liquid you desire. You may wish to manufacture a simple basket with a handle to place the hot rocks in to lower them into the liquid with, thus making them easier to remove. In prehistoric times soapstone was shaped and a hole drilled in each rock to make them easy to 'hook' with a stick for moving. If you have soapstone, it is still the best choice and is less likely to explode. If purifying water, boil for at least five minutes. Making a stew is one of the best ways to get the maximum nutrition from several small items, if you drink the broth, after eating all the vegetables and meats. Many find insects more palatable to eat this way, in a survival situation. For they may be roasted and ground to a powder and then added to the stew to thicken it.

#### PARCHING

Nuts, berries, seeds, tubers and such may be parched in a basket or bowl by shaking them around in a container with some hot coals until done. They may then be eaten or ground up and added to stews. In a survival situation, insects may also be cooked in this manner. When eating any insects, legs, wings and heads should be removed, as these may get caught in your throat.

#### PLANK COOKING

Fish and small animals or slabs of meat may be cooked on a board or plank by securing the meat to the board by tying it or pegging it in some manner. The board with meat secured to it is then placed near the fire, with the meat exposed to the heat until done. Do not use a treated board or sappy pine. The treated board can impart toxic elements to the meat and the pine can give the meat a funny taste. You may also wish to

use a reflector in conjunction with this method of cooking.

#### THE BAMBOO STEAMER

My friend, 'Mountain' Mel Dewese from Grand Junction, Colorado taught me this one. He learned it from the Negritos in the Philippine Islands. He tells me that several of these cylinders were made up and filled with rice and carried on the trail and not broken open until they were hungry enough to eat. You will probably need to refer to the drawing for constructing this item. A joint of bamboo is cut leaving the ends closed on each end by cutting on the other side of the two joints that will form the ends. A 'door' is then cut at acute angles and carefully removed for it will need to be placed back in place. The tube is then half filled with rice and half filled with water. You may also add herbs or bits of meat. The door is then placed back in place. You then sit the bamboo cooker on top of a bed of hot coals with the door facing up and just let it cook. The bamboo will scorch on the outside some but does not burn through due to the fact that the water inside is absorbing the heat faster. It's kind of like that old Boy Scout trick, boiling water in a paper cup. Occasionally check to see if the rice is cooked by shaking the tube enough to be able to tell if there is any more water inside. When there is not enough water to slosh around inside then the cooker should be removed and allowed to cool enough to touch before opening. When ready to eat, just split the entire length of the tube for two delicious, steamed trays of rice! This also works well with dehydrated foods.

#### SMOKING RACK

Tony Breda, a Wapanoag from Towson, Maryland showed me this method of cooking that I have used numerous times and with many kinds of meat since. Again, referring to the illustration when constructing this rack will help you. Lash together two tripods that will stand independently. Now lash as many horizontal poles across the front and back as you will need to cook on. There is no need to make this rack any larger or taller than you will need for the amount of meat you have to cook. Now lay strips of meat you wish to cook along the length of the poles draping down over either side of the pole. Fish cook really well on this rack too. Just cut fresh fish open, eviscerate, spread open and break the backbone in several places. Do not skin them for the skin will help to hold the meat together as it cooks. Lay the open fish over the rack with

meat side out and skin side down. The rack should be placed near your fire where the meat will catch the smoke coming off of the fire. As your fire burns down coals, place a layer of coals beneath the rack, also. This is a slow cooking process that smokes the meat and flavors it to perfection and the smoke keeps away insects while it is cooking. You may also cook the meat to the point that it dries into jerky, if you wish, so it is also a good way to preserve meat for later. Dried fish is not that tasty, however, but dried fish may be ground, bones and all, into a powder that can be added to stews later for the nourishment.

#### BEANHOLE COOKING

This is a little more modern a method of cooking, in that it requires you use a metal pot. It is similar to the steam pit though, in that a pit must be dug a little larger than the size of the pot. You may line the pit with rocks, if you wish. It is not necessary, but it is more efficient. A fire is built in the pit burning down to coals and drying out and imparting heat to the dirt around it. A bed of coals is left in the pit. You may even wish to throw some rocks in with the coals to absorb heat. The pot containing stew or whatever you are cooking is then placed in the pit and coals are built up around the covered pot and on the lid of it. The pit is then covered with dirt and allowed to cook until done. This method acts rather like a crock pot, so you may wish to familiarize yourself with some crock pot recipes for trying out this cooking method. Like the steam pit, once you get the pot buried, you can come back six to eight hours later to a hot meal you didn't have to attend. You may wish to leave the pit uncovered and place several pieces of kindling around the pot, one end down in the coals, the other sticking out. These will burn down gradually on their own and will keep you from having to attend the fire all the while, however you cannot just leave it totally unattended, as you did in burying it. When using this method it is also a good idea to rotate the pot frequently one quarter of a turn clockwise and the lid one quarter of a turn counter clockwise to assure even heat distribution, especially in the case of hot spots in evergreen coals.

#### CHIPPEWA KITCHEN

A very convenient item to build for a long term camp is the Chippewa kitchen. It is a large quadripod, as tall as you wish with a shelf extended to one side. This shelf is then covered with mud and allowed to dry

after forming two small, bowl shaped depressions in the clay. These depressions are used to place hot coals in and allow you the ease of standing as you cook on them, much like the burners on your stove at home. You may then place your pots right on the 'burners' as you cook. You can also place the entire assembly near your cook fire, thus allowing a string to dangle from the center for suspending cooking meat or a pot hook.

These are but some of many methods of outdoor cooking that are available to the innovative woodsman. I am sure as you practice these you will devise many others and improve upon these. They may also greatly lighten your pack load by keeping you from carrying so many pots and pans because you won't need as many. So, enjoy the wilderness!

When I was a boy scout we took a whole chicken(thawed), washed it out with water, then stuffed a fire heated rock into the body cavity. This was then stuffed into a couple of layers of newsprint and a plastic cooking bag, the whole package was then carried in yopur backpack. Then you went on a long hike, several hours later, you would have a cooked chicken. The problem was when you hadn't heated the rock hot enough, or cooked the chicken long enough. Banana leaves, grape leaves, or other similar material can take the place of the newsprint and plastic bag.

James,

I'll bet that was a fun experience for you as a Scout...but in real life,  
is this a practical survival method?

Considering just how much energy is needed to heat the rocks, for how  
long,ect. Then to have to lug a 2# bird, with 3# or more of rocks...more  
energy expended.

I would think that maybe the way, if camp site is to be used a day or  
few, would be to heat rocks during nite, ect., stuff meat with stones on  
the next day, leave a site, and while you are out and about, meat is  
cooking and ready for your return.

Tom's "do nothing" sounds a bit more practical.

It takes energy to get energy.

I recall an article where the author determined how many BTUs it took to cut his lawn... using a power mower and also a non-power mower. Until that article, I never really thought too much about "power balance".

So, in a primitive survival situation, smart conservation of resources would seem #1. IMHO, 'natch.

Perhaps slightly off the list subject, but one of the things being promoted in many of the third world countries is solar cookers. They are easy to cobble up out of available materials (saw an example of one made from straw) the only technical materials being glass plate, a dark metal pot, and aluminum foil. Highly polished metal plate could take the place of the aluminum foil. One of the things they will do is pasteurize water. The box type is bulky to carry, but the panel type would be good for travel, but you would have to add a oven type plastic bag(subtracting the glass) Temperatures up to 300 degrees, and they are good for baking bread, cooking meals, etc. as well. Mainly they are being promoted to prevent deforestation.

I'm all for that and I'll take a dozen. Have you seen the large collection of construction plans for these devices at the website for The Solar Cooking Archives? Serious project material for box, panel and parabolic cookers and pasteurizers.

>>Somehow I doubt they will work in Buffalo...  
>>  
>>Phil

To quote from "Solar cooking for Free" by Christopher Nyerges in the  
June/July 1994 issue of MOTHER EARTH NEWS  
" In fact, solar cookers are practical in every state of the Union(except  
Alaska) for at least six to eight months every year. Even with snow on the  
ground, you'll be able to cook if the day is sunny." This article also has  
plans for a solar cooker made from cardboard. Solar cooker plans are also  
available on the net for a variety of types, box, parabolic, and panel. try  
the following url  
<http://www.accessone.com/~sbcn/> for more plans on the web.

Hi everyone,

Sorry for the delay in posting this information on 25 basic food staples for

walkabouts which I had promised several days ago. I forgot that I had to translate it first, and also that I had to reformat the Exel file for this media. Anyhow, here it is, finally.

I will be pleased to answer any questions related to this. The data herein presented is based on research conducted over a period of 12 years where I was responsible for planning thousands of expeditions from 10 to 54 days in duration for summer camps in northern Ontario and QuÈbec.

A chef can prepare just about any modern recipe using the 25 ingredients listed below. Hope this makes your less than primitive walkabouts more enjoyable!

Cheers,

AndrÈ

Note: you may have to widen your Netscape window to view the table correctly, and you also have to use a monospaced font such as Monaco or Courier.

|    |            | Kilocalories         |      | 3600 | 2800 | 4000 |

Condiments:

Coffee  
Tea  
Lemon juice  
Baking powder  
Dried yeast  
Cornstarch  
Soya sauce  
Chicken base  
Beef base

Spices:

Salt  
Pepper  
Cinnamon  
Curry  
Chili  
Dried mustard  
Assorted herbs

Example of how to use this table: 10 day trip with two men, one woman

To calculate flour needs, add  $(180*2) + (140*1) = 500$  mult X 10 days = 5000 grams or 5kg (or  $5*2.2=11.1$  lbs) of flour

Notes:

The quantities suggested are sufficient for trips where no other food is available. The quantities can be reduced by the amount to be gathered in the wilds. However, the amount of food which it is possible to gather in the wilds is always overestimated. This can cut a trip short, so do not guess at your realistic food gathering capacity.

Do not mix fruits together before packaging. Instead, place in tall narrow bags in layers for variety as the trip progresses, starting with smaller items on bottom. Example, layer raisins, dates, apricots, pears, apples. That way you start the trip eating apples, then apples & pears, then pears, then pears & apricots, then apricots, then apricots & dates, then dates, then dates & raisins, to finish the trip eating raisins only. The same formula applies to juice powders, whole-wheat/white flour, nuts, herbs, and oatmeal/other grains.

Long and wide egg noodles will do for noodle dishes and will double for spaghetti or lasagna, and when broken into small pieces, for macaroni or soup noodles.

Fresh onions will last for months if left unwrapped in a mesh bag. Chefs will tell you that browned onion is the most important basic flavor in cooking, and dried onion

just doesn't work to give that homemade taste.

Fresh eggs will keep for months if left in the shell, even in summer.

Milk powder is very important for nutrition. You don't have to drink it. Add it to breads, bannock, cheese dishes, cakes etc.

Fresh cheese will keep for a long time if wrapped in cloth saturated with baking soda. Waxed cheese and old cheese also last a long time. Moldy cheese is still good if you cut off the mold.

Dried salami and pepperoni last a long time, as do some old fashioned cured hams and bacon. They will last even longer if wrapped in cloth saturated with vinegar. Pemmican and beef jerky are great.

Salted meat is either salt pork which makes great dishes when cut into small pieces and fried with onions as the start to various meals, or salted fish, which are added to rice or noodles.

Canned meat should be in oil, such as tuna fish, for maximum calories per weight.

Fat can be used for deep frying while there is a lot, for making donuts, fish batter, fruit fritters etc., as long as it is strained after each use. When there isn't enough left for deep frying, use for frying or add to cakes, breads, bannocks, oatmeal etc.

The proportions of the different items are the suggestions of the author and will work out if a typical outdoor menu is followed. Midway through the trip and again near the end, an evaluation of proportions consumed vs proportions at-the-start will permit the cook to modify his menu accordingly. To a certain extent, the user may wish to modify item proportions within one category or even within multiple categories by adding and subtracting identical amounts.

The advantages of this system as opposed to pre-packaging meal by meal are twofold:

1. You can pack food for the entire trip in a couple of hours and leave.
2. You have complete cooking liberty: "What do you feel like having tonight?"

Of course, you have to know how to cook when you use this system. But when you do, it feels so much more like living out there rather than bringing city food with you.

Happy wandering!

Yucca fiber wadded up and dried is a great wash cloth too! I bought one at an Indian village in Mexico (close to Tamilpas) and wish I'd bought a case!

Try it both ways, drying first and not. As I remember the leaves are pounded on a metate, (Read as pounded just enough to crush the leaf and separate the fibers, no jackhammers allowed!) Then the fibers are separated and dried. Of course they are hung on previously dried yucca fibers

Now, save the sap for soap and shampoo (high saponin content), and if it starts to ferment, well save that too, for medicinal purposes only...of course!

The point at the end of the leaf can be bent and pulled 'till it separates from the leaf except for a fiber that'll stay with it. Pull this fiber carefully back to the base of the leaf and you'll have a pretty good needle and a foot or two of thread. Saw this done in Mexico at a tequila factory tour and I don't remember whether to pull the point up, as the leaf grows, or down. I guess you'll just have to try this stuff. (I know, I know, tough assignment, but someone has to do it! :) :) :) ) You need to see the needle

and thread to believe what the effect is.

Take Care  
Merv

Yucca stalks are practically all fiber, too. See if you can pound some of that down, if you ever take one down.

Odd cactus handling story:

Friend of mine named John lives in a place called Millard Canyon in the Southern Californian mountains (used to live right there, too). Place is frequented by Christopher Nyerges (gratuitous plug here):

School for Self Reliance <http://home.earthlink.net/~nyerges/>

Anyway, John's a big wild man and takes his chainsaw to a whole hillside of Maguey cactus at his cabin (big jade green - sometimes green and yellow - 5 ft. long sword leafed pointy thing they make tequila with). The cactus juice aerosolized all over the place until he went anaphylactic and nearly died. OK, well...take the machete route, like they do in Mexico. That's my advice. I've stripped off fiber strings from the tip and this stuff is great, though I haven't used it for needle and thread work - crossed my mind. Funny thing, I lived across the creek and my other neighbor was an animal importer with a large glassed rain forest habitat full of those tiny fluorescent-colored poison Panamanian tree frogs you guys have been writing the Cuna Indians rub on their blowgun darts. Guess you can buy them and breed them... 'course he had cobra's there and the rattler's lived loose in the yard.

Chris

I had to look for a reference to find this,PRIMITIVE FIRE AND CORDAGE by John McPherson stated "The leaf of the yucca gives the strongest cordage of any of the plant fibers that I have worked. It is also easy to work. It has the added advantage of being usable when green or dried. With the yucca leaf, the fibers are in the inside. Take the dried leaf and beat it gently to seperate the fibers some. This helps it to soften faster while soaking. Then soak the pounded leaves until they are supple. When like green,or if green, take a rounded knife blade( flint or other wise) and scrape the outer covering from both sides(the soaking makes this easier with dried leaves). Then work the fibers loose by rubbing back and forth with your fingers. Superb cordage material."

Barry Keegan is a good friend of mine that wrote an excellent article in our TRIBE newsletter. He is a very skilled survival and wilderness living skills instructor. He wrote the following excellent article on the subject of making strings for bow and drill firemaking sets. I think you all will find it extremely informative. Also if anyone is in the NY area, check out his excellent classes. Information on contacting him follows his article.

-----  
FAST, SURVIVAL BOW DRILL STRINGS

Why Spend Time Fiddling With Your Bow?

By Barry Keegan

©Barry Keegan 1996

WHY BOW DRILL?

The hand drill fire is the fastest means of making fire: if you must start from scratch. I found this to be true in arid environments or seasons of drought. New York State is far from being arid! After years of practicing the hand drill fire I have reached MY physical limitations. I was finally able to make hand drill fires with a spindle and fire board of very dry Mockernut Hickory (our most dense native wood) but I still couldn't make fire with a damp Mullein stalk spindle on a willow fire board.

Using a bow drill to make fire is more reliable than a hand drill. Because of this climate, damp wood may be all that I have to work with. The problem, though, is finding a good bow drill string that won't take long to make or find! This was a lot of work and lead me to rediscover what can be used.

WHY PLANTS?

I limited my self to plant fibers because in a survival situation I can't always rely on animal products to be available for cordage material. For clarity's sake I will rank these bow drill strings in categories beginning with the most year-round available cordage and ending with the most specialized and seasonal ones. Tree bark, branch bark and root bark, roots, wood, stalk fibers, leaf fibers, vines and runners.

## TREE BARKS

I will begin with tree barks because they are available when the ground is covered by even the deepest of snow. Tree barks also happen to make some of the strongest cords and most of the good ones can be peeled at any time of year. I list tree barks in two categories: Branch barks and Root barks, because each behaves differently and are often handled differently.

### Branch Barks

"Branch Barks" is the category of bark that comes from any part of the tree that is not a root. However, certain parts of the tree provide far stronger bark than others. Select a shoot or branch that is somewhat straight, preferably with no branches, scars, dead spots or any such flaws that interrupt the bark fibers. The branch should be about three feet long and at least thumb thickness to obtain enough bark for a cord. Avoid very tapered branches. Do pick a healthy branch, dying trees have dying bark and work about as good as they look. Knot holes in bark strings may cause separations that tear out during use. What kind of tree you use is of major importance.

The strongest bow drill string of tree bark fiber in New York also happens to be one of the easiest to make. Mockernut and Pignut Hickory work better than other hickories and are my favorite choices!

### Peeling Bark

As a general rule, May 1 through August 1 is peeling season: the time of year that bark peels easiest from trees! This is not a long season but farther south it may be longer. The Basswood tree has its own season which starts earlier and ends later than others. Basswood is the easiest to peel at any time of year. There are three methods that I know of to remove bark at any time of year. None of these methods are necessary during peeling season unless you have an unusually difficult branch.

To obtain bark out of "peeling season", you may use pounding, split-separation or if we weren't trying to make a fire, we could use the fire to carefully roast or steam the bark off.

I will begin by discussing the easiest of these methods and end with the most difficult. I will not discuss the roasting method for obvious reasons.

### Peeling In Season

Cut or abrade off your branch of choice and remove any twigs or branchlets, if you have them. On the cut end try to peel the bark free, as if to begin peeling a banana. If it easily separates, and it should, examine the branch for knot holes or areas of removed twigs. You may want to use a sharp stone flake or knife to score the entire length of the branch to make two or three bark strips of even width and as little taper as possible. This is the best way if you did have branchlets on your branch because you can make the cuts align with the branch scars. Holes in your bark strips are less of a problem if they are on the edge of the strip instead of the center.

Careful peeling can produce good results without scoring if you peel both or all three sides at the same time. You need at least two feet of cord from this branch so go slowly and carefully. Watch for sticky spots! Knots can be very sticky. Pull the bark strip at a 35 degree angle or less from its branch to minimize the tapering tear. Pulling

straight up (90 degrees) or back on itself (180 degrees) will drastically increase the taper or tear out. Sometimes rocking the strip back and forth as you pull on it can free up the bark at a sticky knot area. If it still sticks, consult the pounding section of this article for another way.

Once in a while I find a branch that won't peel, even in peeling season! Trees can be as different as people are, so, if this happens, find another tree or at least a healthier branch. Peel your bark right away or store the branch completely under water until peeled. Elm bark may not peel the next day after it has been cut. Hickory may not peel after being cut three days before and is noted to stick in times of draught, especially on high hills. On the contrary, Basswood may still peel a month after being cut if it sat in a damp shady place.

As a general rule, the youngest branch or shoot that grew the longest length in the shortest amount of time produces the best bark! Some trees like Aspens will give strong bark only on its one year old growth. Good luck finding long straight Aspen twigs that are big enough to provide enough bark to make a sturdy bow drill string. I had to peel 25 ordinary sized twigs to make mine!

If a branch broke off about two years ago and a bunch of sprouts grew from that wound, there may be enough bark on one of these sprouts to make six bow drill strings. Arrow and basket makers purposely cut back Willows and other plants to force them to grow more suitable shoots for materials. This is called copusing! The deer or a storm may have done some copusing for you. If you know your trees well, i.e. Willows grow by water and deer go there a lot, you may find some choice sprouts growing from a broken "buck-rubbed" branch. Beaver love to eat Aspen!

#### Pounding Bark "Out of Season"

If the bark doesn't peel from your branch, find a smooth stone or smooth the bark off of a dead log, this will be your anvil. Then find a sturdy branch of wrist diameter for your pounding mallet. Break it to a one foot length. Scrape your anvil and mallet smooth of any protrusions that may injure the bark that you pound.

Lay the branch across the anvil and begin pounding at the thick end of your branch. Pound till the bark separates on all sides. You need to strike hard, but not so hard that the bark gets crushed. Work down about six inches of the branch's length, pounding every inch or so on at least two of its sides. The bark does separate from the mallet side as well as the anvil side of each blow, if the strike is well centered.

Once you get the feel for how much or little pounding is needed, you can pound the whole branch and then peel it, of course, going slowly to watch for sticky spots. Pound where it sticks till it pulls free easily. If you pull the bark hard past where it sticks you may leave the strongest part of your cord stuck to the branch as the bark tears out thinner.

If it is close to peeling season and the bark sticks, you may score the bark before pounding. Little pounding is needed at this time to remove the bark. In mid winter you will have to pound the bark so hard that it will split where it wants and you will have to choose from what you are left with. At times you may have to pound so hard that the branch becomes splinters! Hickory bark is very tough and can take a lot more beating than other "cordage grade" tree barks.

Hickory and Basswood are the easiest branch barks to remove by pounding because they don't crush easily under the mallet. Gentle mallet work can help remove the bark from Pawpaw, Elm (Slippery and American),

Tulip Poplar and Willow. These barks are more delicate! Try working with one to three inch diameter branches because the bark is thicker on bigger growth and can withstand more mallet work. However, pounding becomes ineffective on branches that are more than three inches thick.

You should have no problem obtaining at least one, hopefully two or three, full length bark strips from your branch. Even if the worst happens and your bark as well as your branch are in splinters, save those splinters and keep reading, you can still make a string!

#### Split - Separation In or Out of "Peeling Season"

Once you have learned the split-separation peeling method you may never pound bark again! Now you can peel bark (if you haven't already). This method of peeling may require a lot more practice than pounding but you will be able to peel bark from nearly all of the cordage grade trees at any time of year! Take your thumb-thick branch from a tree or bush by abrading half way through its top side. Then pull down on the branch so it splits and make the split run about two inches down the desired end of the branch. Then abrade the branch off. You need to split the whole branch in half.

Any split-shoot basketry book or article will show you how to do this, but, basically you need to pull with equal pressure and angles on both halves of the split to guide the split down the stick. If one side becomes thicker, pull it at an increased angle to steer the split back to center. This is a faster way to make two equal sized strips without using a stone flake to score the branch. A branch that is thicker than a thumb may be split in three by splitting and pulling on all three splits at once or also split into four by halving the halves.

Remove bark by snapping the split stick near the center very slowly by bending it in both hands, pressing your thumbs on the bark side and bending away so it breaks down to the bark, revealing it. Next bend the break at a 35 degree angle so the wood that clings to the bark peels away from the bark. Then, if you're a righty, hold the branch at the crack, in your left hand so it lays along your left arm down to your elbow and with your right hand, lift and pull away the wood from the bark.

You want the bark to stay flat and taut. Just as if guiding a split, you need to pull on the wood part of the branch so it does all of the bending because it is much thicker than the bark. This should look like a backwards, small letter "y". If the branch cracks or breaks off, peel up the next section as you did the last, from where it broke off. Keep peeling it like this until all of the wood is removed from that half of the stick.

Then flip the branch around so you are holding the peeled bark in your left hand and the stick part lays along your left arm, as before, and remove the rest of the wood from the bark. With practice this can be done in two or three minutes.

You may lose some bark to splintering on its outer edges. This is less likely to happen if you split the branch into thirds or fourths because the flatter the bark lays on its branch, the easier it is to pull free. Imagine peeling masking tape from a wall compared to peeling it from a pencil which has been covered with a length-wise strip of tape and the edges wrap all of the way around.

Remove the splinters from your bark strips by pulling the bark splinter at a 180 degree angle (back over onto itself). This causes it to intentionally tear out without tearing far at all. Woods that are

flexible, like Willows (especially shrubs), will allow you to split a branch in half, third or fourth down along its growth ring(s) so the wood part of the branch is about as thick as the bark is. This makes it easier to separate the bark without breaking the wood part as much. Butternut or White Walnut are too fragile to be pounded but may give strong cordage when peeled in this manner. Even in January it provides a strip whose strength compares to some Hickories. Do remove the outer bark when using Butternut, Mulberry, Osage Orange, Aspen or any bark that won't twist without cracking the outer bark. Outer bark may be removed by scraping with a stone flake or by abrading it off on a gritty rock, but the fastest method leaves you with the strongest results: split-separation! Split the outer bark from the inner bark at one end by using a sharp edge or bend the bark so the outer part snaps away from you. Then peel up a section and split it in half as you would split a branch, by pulling with equal tension and angles on both halves.

#### Root Bark

I will discuss how to dig, find and select roots for cordage later in this article. How many branches are on your root is not as important for root bark as it is for root wood or branch bark strings. Hickory root bark is the strongest of the root barks. It is as strong, if not stronger, than its branch bark and is easier to remove.

Hickory, Walnut, Osage Orange, Red Cedar and some of the Elms and Cherries have root bark that is much stronger than the wood part of their roots. With Mulberry, Black Locust, Willow, American Elm and Hemlock, their root barks and root-wood fibers can be equally as strong. I have found some variations of strength within species and environments.

With the exception of Hickory, the root barks listed above share a unique characteristic unlike any other local plant fiber cordages: elasticity! A root bark bow drill string can stretch up to two inches when pulled tight. Because of its elasticity bow drill strings of root bark do not need to be as thick as those of branch bark. A thumb-thick root is overkill and a pinky-thick root is ideal. For an example of extreme strength I made a fire with a Hemlock tree's root bark string, taken from a root which was half as thick as a pencil. The string itself was as wide as a strand of spaghetti.

To remove root bark, first cut your root and remove its smaller branches. Hang the root over a branch and hold it by both ends as if you were using it to saw the branch. A branch with toothy bark is ideal but do remove any sharp protrusions that may cut the root or its bark. Buff through the root bark on one side by pulling the root in a back and forth sawing motion. As soon as you've exposed the wood core down the whole root's length, pry the inner root gently out of its bark sheath. Peel the bark from the root at the same 35 degree angle that you would to remove tree bark.

Root bark peels easiest in bark peeling season. It peels almost as easily when out of season! You do not need to pound roots to remove their bark. Split-separation does work on roots but it's not necessary. Walnut is one of the few root barks that needs to be separated from its brittle outer bark. Most of the root barks listed here may be used "as is" for bow drill strings. Root bark is a better choice than branch bark when it's available.

-----  
Barry Keegan and his partner Anthony Follari operate a school in Elmsford, NY called PATHWAYS that teaches a variety of primitive,

survival and wilderness living skills. If you wish to contact Barry or would like a brochure of classes they have to offer, write or call:  
Barry Keegan, 6 Heather Lane, Elmsford, NY 100523, Phone: (914) 592-8961.

As a follow-up to Merv's Ropewalk page, I'd just like to mention that my students and I once made an 80 foot rope from grass using a made-on-the-spot rope machine and then dropped it down a cliff. After hanging 4 persons on the rope to test it's strength, we each took turns at primitive rappelling down the cliff with the rope. Made for some great primitive pictures, especially the half nude shots! Rough on the skin though...

That was a long time ago, and now I would not do this without a real climbing rope for protection. But in a pinch, I can vouch for the strength of such ropes!

Hi

I promised this sooner, but partied too long this Christmas. Ah well, I hear that the Creator really didn't do it in seven days either. Nope, he partied six and pulled an all nighter. :) :) :)

Anyhow, from "Bushcraft" by Richard Graves ISBN 0-446-85491-3.

And probably breaking copywrite by putting it here. Check this page out. It's how to build a rope walk. A rope building machine, some estimated breaking strengths and fun things to do with the rope you've made.

If anyone needs or just would like more info on rappel and ascent via rope, I'm a dedicated caver and know a little about it. There may be more info here on the list. I wouldn't doubt it from the intro's I've seen. Iffen you all had patches for your quals, you wouldn't need clothes!

Anyhow, here's the URL

<http://www.midtown.net/~merv/mropwalk.htm>

Take Good Care  
Merv

p.s. This goes especially if you try any of the rappel or ascent techniques shown on this page. Talk to me first!!!!!!!

Subject: Sinew processing and bow string

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

Just a question.....

I've made a few long bows over the years and I've always tried to use sinew strings on them. The strings work for a few months and then blow. I was wondering if anyone had any suggestions on the preparation of the sinew that might enhance it's longevity.

Of the techniques I've tried, this is what has been working best for me:

Use a tendon from a cow's neck or rear leg.  
Scrape to clean it of loose material.  
Urine soak for 24-48 hours.  
Wash thouroughly with clear water, dry.  
Set aside for months in a clean,dry dark place.

After the tendon looks translucent, I break it down to the fibers by pounding and/or stripping.

I double twist the fibers to make the string. Once the string is set, I soak it in my mouth for an hour or two. The saliva seems to bind the string.

I make the end loops for the bow limbs and serve these with more tendon. Thats it.

Any suggestions?

I've had lots of problems with sinew as a bow string also. I don't use it for that purpose anymore. I use it for other bindings like on arrow points, hafting stone blades, etc. I prefer rawhide and you may want to try spiral cutting the neck hide of snapping turtle, makes a nice strong string. Just strip it off and clean it up with a knife or something and cord it. Don't cook it off. That probably doesn't answer your question on sinew, but I thought I'd comment.

Subject: cordage  
Content-Type: text  
X-Mozilla-Status: 0001

A week or so back, someone in the group inquired about cordage. Haven't noticed any posts in response, so will to pass on some info.

As far as techniques, the information on the Native Tech web site is as good as any.

[http://www.lib.uconn.edu/native\\_tech](http://www.lib.uconn.edu/native_tech)

Follow their links to cordage. They do a good job on the technique, with step-by-step illustrations. Their info on fibers is less helpfull, basically just a listing with illustrations of finished cord which all look about the same. There is a lot of other good stuff at this site.

I will try to give a bit of more detailed information on fiber types.

I will avoid more technical terminology as much as possible and just say that fibers can be grouped into three general groups, animal fibers (sinew, rawhide, hair), tree bark fibers, and herbaceous plant fibers. I will only discuss the last two groups for now.

#### TREE BARK FIBERS

These generally consist of the inner bark portion. Two of the most usefull tree bark fibers are cedar and basswood. Since I don't have much experience with cedar, I will only give detailed info on basswood fiber.

Basswood (*Tilia americana*) is found throughout most of eastern North America where hardwood forests are present. I believe other species of the genus are found in parts of Europe. Although, in a pinch it is possible to collect some basswood fiber most of the year (really tough when frozen), it is best gathered in early summer when the sap is flowing. The trees often grow in clumps, so I usually select a 4 to 6 inch tree from a clump and cut it down (don't be too concerned about this, since these clumps naturally thin out as they grow bigger anyway - you are just helping nature). I pry the bark off starting at the base in 2 to 4 inch wide strips. These easily peel up the tree. After the first strip, it is easier to get really long strips.

After the strips are gathered, bundle them up in a long bunch and soak them in a lake or stream for 2 to 3 weeks. After enough time you will notice that they get really slimy (mucilagous) and the inner layers of bark start to separate. When the inner bark gets really loose, strip it off and run through your hand to remove the slime. Keep all of the layers together, you can separate them when you get ready to use. You will notice that the innermost layers are the thinnest and smoothest. Roll into coils and dry.

It will store indefinitely if kept dry. To use, just separate the layers and make into whatever width strips that you need. Before using, you can boil the strips for a half hour or so to strengthen them slightly.

#### HERBACEOUS PLANT FIBERS

These are typically the fibers in the outer "rind" of the plant stem. Some of the fibers in this group are incredibly strong. Common plants include milkweeds, dogbanes, and nettles. Of these, I favor the wood nettle,

Laportea canadensis, over all of the rest. It has the longest, strongest, and easiest to process fibers. It grows throughout most of eastern North America and perhaps other areas. Unlike stinging nettle, it is native to this part of the world.

Wood nettle favors moist environments and grows best in rather rich soils under hardwood stands. Around here the best nettles grow on the thick black "midden" soils on heavily used archaeological sites located along the shores of large lakes. This material can be gathered any time after the stems have died in the fall. At this time they don't sting any more and the fibers are mature. Just grab them and pull them up, the base of the stem weakens and they pull easily.

Although the fiber can be processed by crushing the dry stems and pulling off the fiber, more and longer fibers are obtained by soaking the stems and stripping off the outer rind. I usually soak bundles in warm water in an old bathtub for a few hours to overnight. After the rind is striped, it should be dried thoroughly and then "broken up" similar to processing backstrap sinew. You can carry the processing step as far as you wish, depending on how soft and fine of fibers you want.

Wood nettle can be gathered for about a six month season in this part of the country. Unlike many plant fibers, it does not deteriorate through the winter, only with warmer, wet weather in late winter and spring. In fact, I just gathered a big bunch Monday. Normally, I gather it in the fall after a good frost, but last fall got too busy. I began weaving a new fabric bag which I will be using for a pottery making demonstration in Saskatchewan in May (need to show the non-believers that the "cord" impressions found on pots are really impressions from fabric bags and not cord-wrapped paddles) and found I didn't have enough fiber to complete it. Since Monday was a nice day (sunny and 20 degrees (F)), we grabbed the snowshoes and took the three mile trek to gather nettle in three foot deep snow, great fun, I will for sure be out this fall. We managed to get 900 stems in about an hour, which will produce about 3 pounds of fiber. I have processed about 1/3 of it so far, and it is as good as gathered in the fall. I plan to use some of the longer fibers for a few bow strings. Most of this fiber is 5 feet long with some 6 feet, really nice stuff. BTW, I gathered some stinging nettle a few weeks back (I could drive to it) and it was unuseable. The fibers were weak and short and did not separate from the stem. I also tried some some dogbane from near the house, but I got a low yield of 1 1/2 to 2 foot fibers (I was trying to avoid the snowdrift venture).

The wood nettle fiber is very strong. You cannot break a less than 1/8 inch twisted cord. It can be processed readily and is suitable for small mammal snares if you can keep them from chewing through. Most of the other herbaceous plant fibers are similar, though in my opinion, less desirable.

I mentioned weaving bags from this stuff. If anyone is interested in this, let me know and I will try to post some details. This all comes from researching impressions on Indigenous ceramics from the area, and is unlike the normal weaving we are used to. It makes a flexible fabric suited to a variety of uses. Anyone for a nettle shirt or sleeping bag?

Good post on cordage Grant.

In my neck of the woods dogbane (*Apocynum androsaemifolium*) makes the best cordage. Simply step on the dead stalks (collected in fall or winter), split, and peel off the inner wood and pith in small chunks leaving the long outer strands. There is a crusty scale on the outermost portion of the fibers that should be removed also, by rubbing between the fingers or hands. Watch out about licking your fingers when working with it as it is poisonous (contains glycosides capable of affecting the cardiovascular system).

Also, I have often found dead basswood trees with old bark that has been naturally retted. Long thin strips of inner bark are there for the picking, but I'm not sure it is as strong as when fresh bark is treated as you suggest. What do you think?

By the way, how many do we have in  
>the group with knowledge of medicinal and edible plants? Please step  
>forward, so we can pick your brains from time to time. I do OK with  
>plants and know enough to survive, but there are so many I know that  
>know so much more than me.

Got info and can dig up a few for ya. It'd be easiest to set up catagories for treatment. Like burns, breaks, upset stomach, aches and pains...

\_DO\_ be careful, a plant called foxglove grows in North America. It's generic name is Digitalis (specificly Digitalis purpurea). Note the name Digitalis. Sounds like heart medicine doesn't it. It's the source of digitalis. That's just one.

One of the basics to carry with you is the bark especially the inner bark (cambium) of the willow. White willow seems to be the best, but all have a chemical called salicine. It's the natural form of aspirin (aceytl-salicylic acid). So whatever you use aspirin for you can substitute wilow bark for. The leaves work too but are a different strength.

Now, be careful collecting the inner bark, If you cut away the cambium layer all the way around the tree (called girdling the tree), you'll kill

it! That's it's blood system.

As far as dosage, I need to dig for some definitions and will post after Christmas.

Speaking of that Merry Christmas to all and to all a prosperous New Year.

Merv

Hi everyone,

If you have been following the potassium nitrate thread and are now out to experiment with bat droppings, please be aware of the following disease which I personally contracted in bat caves in the Yucatan peninsula of Mexico on a caving expedition I did there in 1983.

"Hystoplasmosis" is contracted when coming into contact with old dried-up bat droppings (I was crawling in the stuff for miles underground). There are microscopic fungi on the scats, which you breathe in. You feel fine for about 2 weeks. Then, back in Canada, you catch a "cold" (or so you think at first). But it's the worst cold you have ever had in your life (wring out the pillows for 3 hours, freeze your nuts off for another 3 hours etc). Next day you feel fine for a while, then it starts over again. Doctors don't know what you've got and give you antibiotics that don't work. What's happening is that the mushrooms are incubating and start growing on your lungs. You feel like hell is in you for 18 days or so, then you are either immune for life (if you're healthy and make it through), or you die if you're old or weak.

Any other spelunker (or caver) will tell you that this disease is fairly common in bat caves. It is also common among pigeon growers, cause pigeon scat has the same problem. Be careful!

The guy with the nice white lungs on the X-Ray machine,

Andr 

Hi

I surfed the Center for Disease Control page at <http://www.cdc.gov> and found this on histoplasmosis. We don't do a lot of bat cave crawling out here in California. Not a lot of bat caves. Anyhow, here's the poop!

Merv

-----  
-----  
Histoplasmosis

What is histoplasmosis?

Histoplasmosis is an infection caused by the fungus *Histoplasma capsulatum*. The symptoms vary greatly but primarily affect the lungs. Occasionally the fungus invades other parts of the body; this form of the disease is called disseminated.

Who gets histoplasmosis?

Anyone can get histoplasmosis. Positive histoplasmin skin tests are seen in as many as 80% of persons living in areas where *H. capsulatum* is common, such as the eastern and central United States, although the majority of these persons may not have a history of symptomatic illness. The chronic, pulmonary form of histoplasmosis is more common in males than in females, and particularly in persons with chronic lung disease; acute, disseminated disease is more frequently seen in immunocompromised persons, such as those with cancer or AIDS.

How is this fungus spread?

The organism grows in soil that has been enriched with bat or bird droppings. It produces spores that can become airborne if the soil is disturbed. Inhalation of these spores may cause

infection. The disease is not acquired through person-to-person transmission.

What are the symptoms of histoplasmosis?

The majority of infected persons have no symptoms. When symptoms occur, they vary widely, depending on the form of disease. The acute, benign respiratory disease is characterized by respiratory symptoms, general malaise, fever, chest pains, and a dry or nonproductive cough. Distinct patterns are seen on chest x-rays. Chronic pulmonary disease resembles chronic pulmonary tuberculosis and progresses over months or years. The disseminated form is usually fatal unless treated.

How soon after exposure do symptoms appear?

If symptoms occur, they will usually appear within 5 to 18 days after exposure; the average is 10 days.

What is the treatment for histoplasmosis?

Specific antifungal medications are used to treat severe cases of acute histoplasmosis and all cases of chronic and disseminated disease. Mild disease usually resolves without treatment. Past infection results in increased, but not complete, resistance to reinfection.

Where is the fungus that causes histoplasmosis found?

*Histoplasma capsulatum* is found throughout the world and is endemic in certain areas of the United States. The organisms often grow in soil around old chicken houses, in caves and areas harboring bats, and around starling and blackbird roosts.

What can be done to prevent the spread of histoplasmosis?

It is not practical to test or decontaminate all sites that are confirmed or may possibly be contaminated with *H. capsulatum*, but the following steps can be taken to minimize exposure:

Avoid areas that may harbor the fungus, i.e., areas with accumulations of bird or bat droppings.

Minimize exposure to dust by spraying with a mist of water before stirring up potentially contaminated sites.

If possible, restrict work in high-risk areas to persons with a positive histoplasmin skin test. When working in such areas, all persons, and in particular persons with negative skin tests, should wear disposable clothing and a face mask capable of filtering out particulate matter above 1 millimicron in diameter.

Sites known to be contaminated can be treated with a formalin solution.

Nitro is a sexy explosive, but not a good one.

It's very dangerous to make. In the late nineteenth century there were nitro-manufacturing plants all over the western US, to make explosives to tame the wilds. Most of these plants eventually exploded, despite their experience and safety precautions.

It's unstable even if you make it successfully.

I have not tried making explosives, but I understand there are more powerful

and safer varieties that can be made more easily.

More importantly,

I don't think this list should be about how to make nitroglycerin.

Phil

Me 2 or 3 - just like how the word rings. Agreed. Bombing and arson are my pet peeves. Take it from a guy who had his bedroom torched with a Molotov Cocktail through his window in the 70's and has noted three pipebomb confiscations within a couple miles in the last year...

We had a nitro plant here, Blew up several years ago. Co had changed names over the past several years...but under COMMERCIAL SOLVENTS name, I believe they were one of the main suppliers of nitro for fuels,ect.

I have friends who are employed by the current name(which excapes me... KOCH...that's it.

Loved using high nitro in my model planes, and dragster....

Yeah, explosives can be fun, but be careful out there, even real pros have blown themselves up often enough. Anyway for those who are really curios I recommend companys like Paladin Press or Loompanics who carry a wide selection of books on this topic. I especially recommend the Improvised Muntions Black Book I + II.

But don't do anything I wouldn't do too ;-)

Hey folks'

About this boomer. While I was at Bragg we took a series of classes in improvised munitions. This material was one of the topics. Because of my experience with it I NEED to issue a word of warning.

Explosives are rated on a number of scales; Volume of gas produced for a given weight of material, The heat of the gas, The speed at which the gas (shockwave) travels through air, The sensitivity to shock and heat (Detonation impetus). There are other issues as well but these are the primary elements.

The material we are talking about is made from household chemicals. DO NOT under any circumstances, make it. Why?

It is illegal

It has a very high gas production ratio. It will cause damage.

It has an extremely high shock speed (@18kfps to 25kfps)

It is extremely sensitive to detonation and may even self-detonate.

In our course we made drop sized volumes. These become crystals. The crystals blow. One drop of the liquid, crystallized, shredded a sheet of

paper. A fly detonated it. Had that drop been on a hand it would have blown the metacarpels into the ground. Reconstruction would only be possible in a computer.

It's uses? very few commerical ones. For counter insurgency (or insurgency) purposes it makes a classic self detonating booby trap/ land mine/room cleaner etc. etc. It is made and transported as a liquid. It is set up and then abandoned. It cannot be disarmed. It is avoided at almost all costs. Initiator explosions are much safer.

Just thought you should know. I suggest we avoid discussing explosives. Sam is soooo paranoid.

Ron Hood

>KMN04 is used in the Medical field to cure Athlete Foot and other fungal >infections. I have also been told when mixed with other Chemicals, it will >also make things go BOOM! I found all this out yesterday from a friend of >mine. Hope it will be of some help to all of you.

Par, Merv

Thank you! I completely spaced! I was thinking of Iodine... I guess that it was the post describing it's use to purify water, wash your hands and turn your hands purple. I didn't even look at the header (self defense, with all this brown stuff flying around) If I had I would have noticed that you were talking about something like potassium magnesium nitrate. I get the stupid dick award for that one. Please accept my apologies. As my penance I will now go eat a steamer. Not a new experience.....

Brown toothed and apologetic.....

>  
> As for poison oak, the potency of the plant varies

As a youth, very affected by poison oak, ivy, sumac, I was given drops to eat on bread. Can't say I noticed any improvement...but I do remember having to dose the various skin outbreaks I had:

tick and chigger bites,

p-oak, p-ivy rashes,

"indian fire" infection...had a diff. treatment for each of these...I got pretty good at telling which sore was what:).

These days, first thing I do is look for the p-ivy/oak...pull it up or just keep away.

My Dad was a red-head and he was never affected. He said that red/blond hair people were seldom bothered...what do you guys have to say on this?

Yes, I also learned that the sap was carried on my clothes, gear, dogs, or brush smoke.

>Peter Bigfoot (Reevis Mountain School, Roosevelt, Arizona) claims to build an  
>immunity to poison ivy (Rhus radicans--I think we're talking about the same plant  
>here) by EATING the green leaves in the spring before they are too potent.

Tom, interesting to see Peter's name on here. I've been taking classes from Tim Corcoran (Headwaters Outdoor School in Santa Cruz, CA), and was bummed that I couldn't get the time off work to do his first Desert Skills class this year, which he's running with Peter Bigfoot. I've heard good things about Peter's knowledge of plants. That business of eating the poison oak sounds a little bit like walking the coals, though.... I'm glad I'm already immune. (Poison oak, by the way, has gone through some name changes. I liked it when it was Toxicodendron radicans, but I think it's currently Rhus diversiloba.)

> hair people were seldom bothered...what do you guys have to say on this?

I was a reddish haired, freckled, pale skinned boy. My reaction to poison ivy/oak/sumac was severe. I don't believe red hair offers much protection.

One year sumac caused both my legs to swell to twice their normal diameter. I spent three weeks in bed under a sheet tent with my legs suspended above towels. The towels needed to be changed each hour as they became saturated with liquid.

My worst encounter was at age sixteen after necking in the woods. We were wearing bathing suits (no, really) and nearly every inch of my skin was affected. Those few square inches spared from direct contact were infected later when I used the bathroom.

After two days I looked like the elephant man! Eyes swollen shut, each finger was a single huge blister with a nail indented at the end. Using the bathroom during the next week was a terrifying adventure.

But how might this story relate to primitive skill? Well, for those of us who react severely to poison ivy/oak/sumac the first skill to master is that of identification of the offending plants.

I spend many days each year hiking in the mountains yet it has been many years since I have had a reaction. I attribute my success to the caution I exercise while in the forest. I know the plants and I avoid contact with them. While this may restrict my freedom somewhat it does enable me to enjoy an environment that might otherwise be too dangerous to explore.

BTW, in the 1950's our family doctor suggested to my mother that I chew several poison ivy leaves each spring to decrease my sensitivity. She declined and I was never inclined to try it. I wonder if it really works...?

I have also never been able to steel myself to try what's said to be an Indian desensitizing routine for poison oak (which has my number). Supposedly you can eat the smallest of the new season P.O.'s green "berries." Gradually increase the size or quantity ingested. Scares the heck out me with out a backup of I.V. or intramuscular Solucortef (cortisone based steroid) with a chaser of I.M. epinephrine (adrenaline shot). I don't want to die . Anyone tried eating shoots leaves or berries of these poisonous plants? One hears these stories, but never hear of any takers. Probably a good example to follow as "dead men tell no tales."

Chris

This is an old lumberjack trick that I read about in a Euell Gibbons book.  
I asked the plant-woman at Tom Brown's school about it (forgot her  
name), and she said that it might work sometimes but she knew one person  
who tried it and got a terrible internal reaction and lifelong sensitivity.

As I was saying before I hit the wrong button while writing my reply. I  
would not try this even with all the medical stuff you talked about.  
Remember even in a hosp, people have died right there in ER from taking meds  
and other stuff that does not agree with them. My MD has said he thinks I'm  
allergic to Penicillin because I once got a rash after taking the drug. I  
have always taken it and I really don't thing I have a problem with  
Penicillin, but I won't take the risk to find out. I would not want to die

trying to prove I was right and the doc was wrong. Same goes for the plants. If you don't know for sure, don't risk it, it is just not worth dying over. After all, the name of the game is survival.

Gary

With your level of sensitivity I wouldn't advise it. I've never had a case of poison Ivy even though it grew rampant in the area of Oklahoma I grew up in. I know I must have come in contact at some time. My sis on the other hand could just walk along a path near it without actually touching it and would get a case. Go figure.

>I was a reddish haired, freckled, pale skinned boy. My reaction to  
>poison ivy/oak/sumac was severe. I don't believe red hair offers much  
>protection.

Hi all,

I am a blond and I am not affected by these nasty plants but I have never believed that it was because of my hair color or ethnic background, just lucky I guess.

I agree, identification is the best place to start in order to avoid bad reactions.

DO NOT try to desensitize yourself by chewing a few leaves!!! From my understanding your mouth and tongue and throat and whatever else internal is just as susceptible as the external.

I have read that eating poison ivy and/or poison oak can be extremely dangerous! I would definitely recommend against it. Apparently those

that have done this successfully are individuals who would not get the infection from plants anyway (strong natural immune systems). Seems that those who are apt normally to get skin infections can also get very bad mouth infections as well. I am not speaking from experience or from medical knowledge here, just what I read I-forgot-where.

BTW, my sympathies for your horrible ordeals. Makes us aware of some of nature's dangers. Thanks for sharing. We'll all be more careful from now on...

well, that brings up the questions:

Is it possible to be desensitized to substances that cause an allergic reactions? If so, how? What are the folks getting that go in for allergy shots? Immune suppressants?

Seems like one of the old homeopathic medicines was poison ivy, but

in very dilute form.

Forgive me if you were only joking, but I'm told you \*do\* actually have to come in  
contact with the plant's oils to come down with a case.

My understanding of how these poisons work is the opposite of what's  
being assumed here. Allergies, you know, are immune responses gone  
amok. Some people have never been sensitized to poison ivy in the  
first place, and so seem immune. But a big dose can create  
a sensitivity that reveals itself on further exposure.  
My father was once immune, so he was given the task of cleaning  
out a big patch of poison ivy. His next exposure caused very  
severe illness.

WEelp, time to jump in. I'm immune. Have always been. To the point that I  
can walk through poison oak in shorts when it's 90 degrees in the shade and  
cut up fallen oak limbs with a chainsaw. I can also slash the poison oak  
back at the same time. The aerosol is pretty thick and I wouldn't advise  
anyone not very immune to get close.

OK enough brag.

Poison oak reaction, as I understand it is more than an allergic reaction.  
it's a reaction to the oils in the plant. Kinda like reacting to mustard gas.  
Now, these oils exist in the pollen and on any dust that drifts off of the  
plant so some very sensitive folks can contract the problem from just  
standing downwind.

Most folks can be around it and not get affected if they wash with cool to  
cold water within one half hour of contact. NEVER HOT!!! (Opens the pores  
and lets in the poison oak oils.) It is an oil also so soap don't hurt.  
Lye or saponin in a survival situation.

The drops are still around and I think they work kinda like eating a bit of  
the plant. the difference is that the drops are always at the same  
concentration. Nice to know if you need them.

I can find the manufacture if anyone wants the info. Also, for partially  
primitive camping and hiking, I would suggest a liquid soap known as "Tecnu"  
Put it on before contact if possible. My sensitive friends swear by it.

(Boy, there's a bunch of straight lines in this post. Don't everyone hit  
me at once :) :) )

Eating the young leaves (berries won't be there in the spring for poison  
oak.) may be a solution, though I'd be kinda chary about trying this if I  
were sensitive to the stuff. The effects can be internal, I believe that

the oils invade the lymphatic system, and it takes steroids to stop it. Not real fun to break out wherever the oils feel like it. Lived with a lady that did this once, her first case and she thought she was immune until we were chopping it back one day...

BTW poison oak makes a wonderful black dye for your woven baskets. The northern californian indians used it quite a bit..

Yeah, when i was in scouts I made a fire and was burning some brush that  
unbeknownst to me had poison something or another in it. The smoke  
blowing in my face gave me a massive rash/blistering/eyes swelled shut.  
I was a mess!! Our ministers boy also got it really bad - we were both  
out of it for about a week. The lesson is - smoke can carry the  
poisonous oils.

Hello guys,

I am hyper sensitive to the poisons...both oak and ivy. And stange as it may seem...you can also get it in the winter from the roots. I dug up some roots in a flower bed on a warm winter day and it was all over me. My doctor was amazed that I had gotten poison ivy in the winter.

As long as there is sap, the poison is going to be active. As I may have mentioned before: shoes, clothes, tools, pets, anything that has come into contact and gets sap can be your source for infection.

I just finished some early-spring yard work, pulled a few roots, but used gloves I can toss, when finished.

And for certain, NEVER BURN THE STUFF. The smoke is active, too! BTDT.

Subject: Lichens

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

I snipped out a section of my Herbal Field Guide to Plant Families (and added some notes) to answer some of the group's questions about lichens, including Usnea. (Lichens are not my stong suit, but I included

the information in my book to help define the difference between lichens and true plants.) The asterisk marks by some of the lichens below indicates that I recognise at least some members of the genus. Any input from the group on these or other lichens would be greatly appreciated.

Lichens are a symbiotic association between algae and fungus. The algae is a layer of single-celled plants on the surface, just below a gelatinized layer of fungal hyphae. The algae captures nutrients that land on it's surface and provide energy through photosynthesis, while the fungus absorbs moisture, and provides a protective structure for the algae. These are otherwise independent organisms, capable of surviving without each other. Lichens can insert threads a half inch into solid rock. These threads are not true roots, but anchors. The fungus produces a potent acid, which is combined with an alcohol from the algae to form acid crystals. The varied and often bright colors of the lichens come from these acid crystals. The acid is used to etch holes in the rock, and threads are inserted for anchors (Platt). Most of the so-called "mosses", especially those found in trees, are actually lichens. The true mosses are distinctively green like other true plants.

Lichens gather most of their nutrients through their surfaces, directly from the air and rain. This habit gives the lichens an adaptability to live almost anywhere, even on rocks, trees, or buildings. On the other hand, lichens are highly susceptible to air-borne pollutants, which they absorb in toxic concentrations. It is challenging to identify the many lichen families and genera. Much of the identification is done using high-powered microscopes or chemical tests, using calcium hypochlorite (like bleaching powder), potassium hydroxide (like "Liquid Plumber"), aqueous potassium iodide (iodine tincture), and paraphenylenediamine (highly toxic). For specific identification of the Lichens, I recommend *How to Know the Lichens* by Mason Hale, or *Mosses, Lichens, & Ferns of Northwest North America* by Dale Vitt, Janet Marsh and Robin Bovey. These books have technical keys, but they also have lots of photographs. For the purposes of this book I have chosen to lump the lichens together to see what patterns are revealed across the division.

The Lichen Division is comprised of at least 8 orders, 45 families, and 6,000 species. Information on the edible and medicinal uses of the lichens is scattered. Many lichens are known to have potent antibiotic

properties, and many are edible. However, some lichens do contain toxic substances, so you should not graze randomly on them. Some lichens can be used to produce brilliant dyes. Litmus was originally derived from several species of *Roccella* found in Africa. Litmus is a purple substance that turns red in acid and blue in alkali.

(The suffix -ACEAE indicates a family. Family members are listed by genus only, not species.)

#### PARMELIALES ORDER

##### GYROPHORACEAE

*Gyrophora* -Rock Tripe: The lichen is edible, especially when boiled with meat (Sturtevant).

*Umbilicaria*-Rock Tripe: This lichen is edible cooked. Soaking in a couple changes of cold water will help to remove the bitterness. They are said to be mucilaginous, great for thickening stews (Angier). It also has antibiotic properties (Angier).

##### LECANORACEAE

*Lecanora*-Cup Moss, Manna: The plants are edible (Sturtevant). One species, growing in the middle-east is the "manna lichen". During drought years the plant may be broken apart by the wind and blown across the land. This lichen became immortalized in the Bible when it showered down on the starving Israelis as the "manna rain".

##### PARMELIACEAE

*Cetraria*-Reindeer Moss: Reindeer moss is bitter, antibiotic, and edible. The lichen is used as an expectorant to stimulate the release of phlegm, apparently due to the bitterness. This bitterness needs to be removed to make the plant edible. The lichen should be soaked over-night and for most of a day, in two changes of cold water to remove the acids, then strained and eaten (Angier). It is a source of gelatin (Asch).

*Parmelia*-The lichen is boiled for use as a dye (Gilmore).

##### USNEACEAE

*Alectoria*-Black Tree Lichen\* The black tree lichen is stringy and "moss" like. Montana Indians washed and soaked the lichen, then cooked it for one

to two days in a steam pit. The cooked lichen was eaten or dried and powdered and used as a mush or thickener later. It is reported that Flathead Indian families ate 25 pounds of the lichen each year (Hart). Evernia- The plant is edible (Sturtevant). A thick tea is used on running sores (Murphey).

Letharia-Wolf Lichen\* This bright yellow tree lichen contains a highly toxic acid. It was once combined with animal fat and nails and used in Europe to kill wolves (Vitt). It is also used as a dye plant.

Usnea-Old Man's Beard\* The lichen is boiled for use as a dye (Gilmore). It is used medicinally as an antibiotic (Klein). (Usnea is a light grey color. Use the "rubberband" test for positive identification: break the stems and inside you will find a white, rubbery core that stretches a little like a rubberband.)

#### PELTIGERALES ORDER

##### STICTACEAE

Sticta - The lichen is edible (Sturtevant).

#### CLADONIALES ORDER

##### CLADONIACEAE

Cladonia-Pixie Cup Lichen\* The Cladonias contain didymic acid, used as an antibiotic against tuberculosis (Mabey). It is reported to be edible (Sturtevant).

Cladina-Reindeer Lichen Some species were boiled and the tea was taken for colds or as a laxativ

Hard to tell from your description, but I doubt it's sphagnum, which is  
the bogforming moss of the northern forrests. The color fits, though.

Anyone familiar with the are and can help out on the possible ID?

Subject: Colorado Wild edible help  
Content-Transfer-Encoding: 7bit  
Content-Type: text/plain; charset=us-ascii  
Status: U  
X-Mozilla-Status: 0001

Hi,

I have recently subscribed to this list and think that there is a lot of good information that is passed around. I have been serious about learning wilderness survival skills for the last three years and because of that interest, I have my scout troop working towards a week long wilderness survival high adventure this summer. We are based in Longmont which is just northeast of Boulder 15 miles.

One of the areas that we need the most help on is with wild edibles. I have Peterson's guide and a Rocky Mountain guide but am interested in still more sources of information. If anyone would be willing to do a field trip or know of someone that would like to do a field trip with either my whole troop or just myself and the other scoutmasters I would really appreciate it. Sometime in may or June would probably be best for a field trip as our trip is currently planned for the third week in July. I am also interested in any other field guides that are skewed towards identification and uses for this area.

We are planning on about 50% of our food coming from foraging. Part of the equipment list for each boy is going to a sock full of whole grains and legumes. We hope to catch fish and also setup non-lethal snares. As leaders we will have a small supply of spices, meat, flour and honey to supplement the food. For example if the boys set up a snare or deadfall on a run and an animal triggers it ( the snares will be designed so that the loop will break as it tightens and the deadfalls will have a

stopper stick) then they will get some meat to throw in their evening stew. A few of the boys have caught trout by hand and all of them have at least touched a trout and made an attempt at catching one.

Also if anyone has good methods for cooking without pots, I would be interested in seeing some posts about them. I have done ashcakes, tortillas on hot rocks and roasting on a stick but have not tried any pit steaming or things like that. We will be taking one big pot along with us but I would like to do at least one day without using the pot.

Thanks.

Mike Jones

I'm sending you a rather lengthy list. I hope you find someone near you.  
I have marked the ones that are a little higher priced with a \$ sign.  
They are worthwhile, though. Most of them have plant knowledge, some as

indicated, specialize in plant knowledge. Also check out the publication below, Wild Foods Forum. Vickie shufer is editor and can help you find someone also. I would also contact Christopher Nyerges at Survival Services below. He is one of the best out your way on plants. Let me know how else I can help!

PRIMITIVE, SURVIVAL AND WILDERNESS LIVING SKILLS TEACHERS:

Barry Keegan, Pathways School, 6 Heather Lane, Elmsford, NY 10523,  
Phone: (914) 592-8961

He and his partner, Anthony Follari are two of the most skilled people I have met. They communicate well and their experience in the field is apparent. Write for a full schedule of their classes.

Bear Thistle, Jim & Gloria Robbins, P.O. Box 429, Dudley GA 31022,  
Phone: (912) 676-4120

Jim and Gloria teach many primitive skills. Primitive drilling techniques, stone carving, basket making, bag weaving and much more. They also sell custom made jewelry.

\$ Boulder Outdoor Survival School, Inc., P.O. Box 1590, Boulder, CO  
80306, Phone: (303) 444-9779

B.O.S.S. has much to offer In primitive and survival skills workshops from a week to 27 day long hands-on training. Write for a schedule of classes and products they have available. They are also a good resource to connect you with some particular craftsman, book or resource you may be having trouble locating. Dave Wescott is director and is well known for his contributions and and skills in primitive and survival technologies. He organizes Rabbit Stick Rendezvous and is editor of the Bulletin of Primitive Technology.

Camp Antiquity, Ken Sherron, 131 Ranch Dr., Ponca City, OK 74601, Phone:  
(405) 765-3722

Training camps in primitive skills. Regular courses include 5 day intensives in brain tanning, flint knapping, friction fire making and cordage. Classes usually run Monday through Friday. Weekend classes by appointment. Family oriented. Drugs and alcohol prohibited.

\$ Errett Callahan, Piltdown Productions, 2 Fredonia Ave., Lynchburg, VA 24503

Errett Callahan specializes in and conducts workshops in flintknapping, primitive skills, archery, etc. and sells stone knives, flintknapping supplies and a starter set for the beginning flintknapper, complete with instructional flashcards. Catalog available. He is very renowned worldwide as an exceptional experimental archaeologist. He is founder of the Society of Primitive Technology.

Eustace Conway, Turtle Island Preserve, Rt.1, Box 249B, Triplet, NC 28686, Phone: (704) 872-7972

Native American Culturalist. School programs, teacher workshops and Museum presentations available on various Native American skills. Braintan hides for sale. Brochure available.

Flintworks, Scott K. Silsby. 6604 Placid St., Falls Church, VA 22043, Phone: (703) 533-0056

Scott is the best teacher and tool maker, when it comes to greenstone tools. He also teaches workshops in flintknapping, bow and arrow making and sells greenstone and greenstone tools.

Hawk Hurst, E.A.R.T.H. Programs, Silver Water Retreat, Hawk's Hoops, 2511 Bald Fork Rd., Todd, NC 28684, Phone: (910) 385-1401

Rainsticks, Bamboo, Gourds and instruments, such as, drums, rattles and flutes, for sale. Hawk Hurst has workshops to offer that allow you to create and build your own drum, flute, rattle and rainstick. They also have E.A.R.T.H. Programs (Earth Awareness programs/Re-experiencing Tribal Heritage), Primitive Skills Summer Camps for-ages 7-12, Wilderness Weekend Survival Treks and Family Camp Weekends. Hawk and his wife Ayal now conduct classes at beautiful Silver Water Retreat A 214 acre site with waterfalls, a refuge for all plant and animal life. Silver Water Retreat offers examples of low Impact, environmentally appropriate technology', environmental skills and many programs through the educational center. It is also a place of seclusion for peaceful retreats and encounters while one explores their own personal creativity. Plans also include a replicated village of primitive shelters from around the world and a community of people to live on site

permanently as part of the program and goals they envision.

HOFUNEE Southeastern Indian Programs, Scott Jones, P.O. Box 2446,  
Athens, GA 30612, Phone: (706) 743-5144

Scott has some very good workshops in various primitive skills. He has appeared on TV on such programs as Earthmatters and Earthnet. He is very skilled and very entertaining. He also sells rivercane for blowguns and arrows.

Jeff Holshouser, 8535 Bringleferry Rd., Salisbury, NC 28146, Phone:  
(704) 639-9082

Jeff teaches some excellent workshops on flintknapping, especially for those just starting out in flintknapping. He also collects artifacts and sells casts of originals and will do other replication.

Jim Lowery, Earth Skills/dirt times, 1113 Cougar Court, HC 2, Box 8132,  
Frazier Park, CA 93225,  
Phone: (805) 245-0318

Jim directs a variety of primitive skills classes and tracking. Also ask about their great little newsletter that focuses on tracking, wilderness skills and nature awareness. It comes out quarterly and focuses on the Southern California area, but has some good information that would be good for any area. Not only do they have articles on tracking, they also have articles on many primitive technologies. Back issues are available and a catalog. Subscription Price is \$12.50 (\$15.00 International)

Jim Riggs, Contact: Lucille Housley, Malheur Field Station, HC72, Box  
260, Princeton, OR 97721, Phone: (503) 493-2629

Specializing in primitive technologies and living skills. Workshops available, write for schedule and locations.

Jim Roberts, 111 W. Trinity Ave., Durham, NC 27701, Phone: (919)  
688-1430

Cross cultural percussionist, hand drum teacher, drum maker,  
instructional tapes for sale.

John C. Campbell Folk School, Brasstown, NC 28902, Phone: 1-800-FOLKSCH

School specializing In various folk and ancient skills and crafts.  
Catalog available.

John McPherson, Prairie Wolf P.O. Box 96, Randolph, KS 66554, Phone:  
(913) 293-5310

Workshops available In various primitive living skills. Books and  
videos for sale.

John White, Ancient Lifeways Institute, Michael Hollow Rd., Michael IL  
62065, Phone: (618) 576-9255

Educational center specializing In Midwestern Native American life  
and skills 300 years ago.

Keith Grenoble, 1012 Madison Lane, Falls Church VA 22046

Keith is very skilled in many different primitive living skills. He  
is an excellent, good natured patient teacher.

Linda Runyon, Wild Foods Co., Inc., 13239 W. Shadow Hills Dr., Sun City  
West, AZ 35375, Phone: (602) 933-8675

Linda Runyon knows edible and medicinal wild plants. Linda learned  
from the Iroquois people while living in the Adirondack wilderness for  
13 years, She was once on Ripley's Believe It or Not TV show for feeding  
200 people a banquet from harvesting a 10 foot square of yard for 15  
minutes a day for three weeks! Wild Foods Classes every Wednesday,  
7-9p.m.

Living History Workshops, The Berkeley Museum, 950 Story Landing Rd.,  
Moncks Corner, SC 29461,

Phone: (803) 899-5101, Contact: Mark Butler

Mark Butler is the program director and has classes in many different  
primitive skills to offer.

ëMountain' Mel Dewese, Learn To Return/Survival Experience Reaction  
Education/Nature Knowledge, 1825 Linden St., Grand Junction, CO 81503,  
Phone: (303) 242-8507

Mel is very highly skilled in many primitive and survival skills. He  
knows more ways to start a fire without matches than anyone I know. He  
has trained Navy SEAL's and various military personnel in tropic,

desert, arctic, mountain and woodland conditions. He is featured on one of the Woodsmoke videos, Fire III. He is not only a good teacher, but is also very entertaining.

Musselshell Traders. Paul & Snowbird Dinsmore, HCR 67, Box 11, Mosby. MT 59058, Phone: (406) 429-7828

Teaches Northwest Coastal Native American (Colville, Kootenai, Blackfoot, Cree) tanning method. wet scrape, smokes, then brains hides. Also sells finished hides and trades 7 scraped hides to 1 finished hide.

Nature & Vision Tracking School, Charles Worsham, RFD 4, Box 446 Thomas Rd., Madison Heights, VA 24572, Phone: (804) 846-1987

If you're looking for classes in tracking Charles Worsham is one of the best. He teaches animal and man tracking. Write for brochure.

Kathleen & Preston Roberts, Rt. 1, Box 200-A, Hays, NC 28635, Phone: (910) 957-3459

Two very skilled and gifted teachers of primitive skills. Preston is also a fine braintanner and makes buckskin clothing.

Steve Watts, Schiele Museum of Natural History, P.O. Box 953, Gastonia, NC 28053, Phone: (704) 866-6912

Director of Southeastern Native American and Aboriginal Studies Program at Schiele Museum. Write for schedule of workshops available in various aboriginal skills with emphasis on the Southeastern Native American. Replicator of Southeastern pottery, points, etc.

Steven 'Snow Bear' Taylor, Yonah Earthskills, Rt. 5, Box 396, Hayesville, NC 28904, Phone: (704) 389-9336

Specializing in primitive and pioneer living skills, edible, utilitarian and medicinal wild plants, tracking, stalking, nature awareness, storytelling, music and primitive cooking. Available for contract work. Brochure available. Co-organizer and founder of annual Earthskills Workshop/Rivercane/ Falling Leaves Rendezvous in Unicoi State Park, Helen, Georgia.

Survival Services, Christopher Nyerges, P.O. Box 41834, Los Angeles, CA 90041, Phone: (213) 255-9502

Wild food outings. Classes in survival. Products.

TACACHALE Programs, Sam Lawson & Ann Gill-Lawson, 871 Willis Lane, Dublin, GA 31021, Phone: (912) 274-9008

ëTacachaleí means ëto light a new fireí. They teach ancient principles and practices through material culture, primitive skills, legends, stories and southeastern ethnohistory in order to bring new understandings in environmental and cultural studies.

The Chapman Log House Building School, Don & Bonnie Chapman, Rt. 8, Box 739, Mooresville, NC 28115, Phone: (704) 663-5080

Don Chapman is a log home builder, artist and historian. He teaches traditional Appalachian log home construction techniques.

Tony Breda, The Swimming Turtle, 1322 Dalton Rd., Towson, MD 21234, Phone: (410) 882-9339

Tony offers classes in edible wild foods, aboriginal daily skills (primitive cooking, hide tanning, shelter construction, etc.), primitive tool making, native fishing techniques (spears, nets, traps, etc.) modern wilderness survival, primitive pottery and basket making, Living with the Earth (survival campouts). Classes at various locations in Maryland, Virginia, Yukon and Great Britain. Also makes and sells great dugout canoes suitable for museums or for using.

TRIBE, P.O. Box 20015, Charlotte, NC 28202, Phone: Benjamin Pressley (704) 827-0723, E-Mail: [tribe@perigee.net](mailto:tribe@perigee.net)

Visit us on the Internet: <http://users.aol.com/tbprim1/Tribe.html>

TRIBE is an organization dedicated to bringing together people interested in primitive technologies on a regional basis and providing a medium whereby knowledge and resources may be shared with one another. This is accomplished through the regional newsletter, TRIBE, the annual primitive skills event, TRIBE GATHERING and co-ordinating with, co-operating with and promoting primitive skills teachers and practitioners of primitive technologies.

TRIBE has a year long schedule of workshops and classes in many primitive, outdoor and survival skills and crafts. We handle some of the best primitive skill instructors in the country. To find out about our

exciting schedule request free TRIBE Information Packet or check out a sample of the newsletter only \$2.50.

TRIBE also offers a service to any primitive, outdoor or survival skill teacher or practitioner that wishes to teach. TRIBE offers their service as a staff, provides promotional literature, advertising, provides students and collects all fees. The guest instructor receives their required fee and TRIBE charges 20% over the guest instructor's required fee. This money pays for expenses of this service and the rest goes back into the organization for future expenses to benefit primitive skill practitioners everywhere who know of and benefit from TRIBE.

Willow Winds, Jim Miller, Director, 962 F-30 West, Mikado, MI 48745,  
,Phone: (517) 736-3487

Jim is an experienced braintanner and offers workshops in braintan and many other primitive skills. He has replicated items for the movies, such as Dances With Wolves, Thunderheart and others. He has braintan buffalo and elk hides available for sell.

Workshops In Primitive Living Skills For Children And Educators, Jeff Gottlieb, 57 Westgate Rd., Massapequa, NY 11762, Phone: (516) 232-2903

Abo Replicas: Shelters, Tools, Games and Toys/ Natural Creations: 'Wild' Baskets, Rattles, Fiber Art Jeff has many programs to offer adults and children and is very qualified. Here are some of his offerings: Life Zones of Planet Earth/ Primitive Technology/ The Deer People/ Wilderness Survival/Ancient Days and Native Ways/ Stories From the Earth Write for price list. "I look at survival and aboriginal living skills as a way to get closer to the Earth, which supports us all as a mother cares for her children. I teach in order to help people reconnect with the web of all life." --Jeff Gottlieb.

THESE MAGAZINES, NEWSLETTERS AND ORGANIZATIONS ARE ALSO A GOOD RESOURCE WITH A LOT OF GOOD INFORMATION TO OFFER AS WELL AS WHERE PEOPLE ADVERTISE CLASSES:

Backwoodsman Magazine, P.O. Box 627, Westcliffe, CO 81252, Phone: (719) 783-9028

"The Magazine for the 20th Century Frontiersman Specializing In

Trapping, Woodslore, Survival, Gardening, Muzzleloading and Homesteading". A great all around magazine! \$15.00 per year. \$28.00 for 2 years.

Backwoods Home Magazine, 1257 Siskiyou Blvd., #213, Ashland, OR 97520, Phone: (805) 647-9341

A really great magazine on all aspects of self reliant living; home building, alternative energy sources, farming/gardening, health, environment, etc.

Boomerang News, Ted E. Bailey, P.O. Box 6076, Ann Arbor, MI 48106  
News on Boomerangs, Rabbit sticks from around the world. \$10.00 per year (\$12.00, Canada. \$20.00 Overseas).

Bulletin of Primitive Technology, Society of Primitive Technology, P.O. Box 905, Rexburg, ID 83440, Phone Voice/FAX: (208) 359-2400

More than a magazine, the official bulletin of the Society of Primitive Technology. The most highly technical, yet understandable, magazine on various primitive technologies I have ever read. Contains articles by all the big names in these technologies. Join the Society and order their back issues while you can at \$10 per issue. Free classifieds for members. \$25.00 year. Subscription price includes annual PrimitiveTechnology Newsletter.

Coltsfoot, Rt. 2, Box 313A, Shipman, VA 22971

A bi-monthly newsletter published in appreciation of wild plants. Contents include articles on edible and medicinal plants. Subscription Rate: \$10.00 per year (Sample Issue: \$2.00)

dirt times, Published by Earth Skills, 1113 Cougar Court, HC 2, Box 8132, Frazier Park, CA 93225,  
Phone: (805) 245-0318, Editor: Jim Lowery

Great little newsletter that focuses on tracking, wilderness skills and nature awareness. It comes out quarterly and focuses on the Southern California area, but has some good information that would be good for any area. Not only do they have articles on tracking, they also have articles on many primitive technologies. Back issues are available and a catalog. Subscription Price is \$12.50 (\$15.00 International)

Herbal Voices, 3936 Mt. Bliss Rd., East Jordan, MI 49727

A quarterly newsletter for plant crafters. It has articles on medicinal plants, edible plants and many other plant related topics. They are also forming a network for people who use herbs. Subscription Rate: \$12.00 per year

Journal of the Great Lakes Primitives, George Hedgepeth, Editor, G-3450 South Linden Rd., Suite 119, Flint, MI 48507

Newsletter on various primitive skills and activity focusing on activity in the Great Lakes area. \$10.00 per year

Michigan Flintknapper's Newsletter, Robert Love, 8185 Kiowah Trail, Pinckney, MI 48169

The newsletter of the Michigan Flintknappers about flintknapping. \$10.00 per year.

Pathways, The Newsletter of the National Association of Therapeutic Wilderness Camps, NATWC, 174 Underwood Farm Rd., Cleveland, GA 30528

This an organization that is a network of camps that uses wilderness living skills as a tool to reach troubled youth with a therapeutically sound, non-punitive approach. They hold an annual conference and have such distinguished members on their board, such as Larry Dean Olsen (ANASAZI Foundation, Outdoor Survival Skills). \$25.00 per year or join their organization with full benefits for \$40.00 (Individual), \$30.00 (Full-time student).

Pow-Wow Listing, John Blackfeather and/or Lynette C. Jeffries, 511 Latimer St, Hillsborough, NC 27278,  
Phone: (919) 732-8512

A one page newsletter that lists Pow-wows going on all over. Subscription price is three self addressed stamped envelopes. send to address indicated,

Pow-Wow Trails, P.O. Box 1188, Long wood, FL 32752-1188

Extensive listings of Pow-Wows and articles. Subscription Price: \$12.00 year--I 2 issues

Prehistoric Antiquities & Archaeological News Quarterly, Dept. 301, Box 53. N. Lewisburg, OH 43060

Prehistoric artifacts for sale and trade, articles on current archaeological findings and research, calendar of events for meeting, auctions and shows, books and supplies. To Subscribe: Sample, \$5. 1 Year Subscription (4 issues). \$20 (Canada \$4. Sample, \$6)

Primitive Archer, P.O. Box 209, Lufkin, TX 75902-0203, Phone: (409) 632-8746.

This magazine is dedicated to the primitive bowyer, hunter and archer. They deal strictly with wooden bows, not compounds, not artificially laminated. Articles on choosing bow woods, flintknapping, constructing bows, tales of hunting and hunting how-to with primitive bows, romance of the bow and primitive hunt, arrow making, resources... just about anything having to do with primitive bow and arrow making, hunting or archery. They also have a bowyer's help line, network exchange of tips and information and opportunities to trade hunts. Subscription price is \$16 per year. Canada \$24, Foreign \$31. Published quarterly.

The Caretaker Gazette, 1845 NW Deane St., Pullman, WA 99163-3509, Phone/FAX: (509) 332-0806, E-mail: [garydunn@pullman.com](mailto:garydunn@pullman.com) Here is an idea worth considering. How would you like to have your housing provided by a landowner and live rent-free with no mortgage obligations? It is possible as a property caretaker. There is an increased demand for property caretakers across the U.S. watching over someone's property in their absence and in some cases on nature retreats, ecological preserves, camps, national and state forests. Thea Dunn is doing a great service and has researched this field and has began a publication called The Caretaker Gazette. If you are interested, this newsletter is worth receiving. Subscription Price: \$15.00 (6 months, 3 issues), \$24.00 (1 year, 6 issues), \$44.00 2 years, 12 issues).

The Cast, 7273 Hamburg Rd., Brighton, MI 48116, Phone: (810) 231-2314

Recently, Lou Becker, Ron Rappaport, George Hedgepeth and Jim Gilligan organized a group called the Michigan Atlatl Association, They have a great newsletter to offer that will keep you informed about the many atlatl and primitive skills events going on in the Great Lakes area. Lou

Becker had the idea of starting an atlatl association in Michigan and they already are planning a boar hunt and some patches with their great looking logo on them. They will be networking with many other groups like TRIBE. It's great to see people getting together and networking, so we can support one another. If you're Interested in joining send \$10.00 dues to: Lou Becker, President, 5940 Urban Dr., East China, MI 48054, Phone: (810) 765-4623.

The C.R.O.W. Call, P.O. Box 187, Bogota, NJ 07603, Phone: (201) 48& 0446

The quarterly newsletter for Children Respecting Our World, A fine newsletter that deals with many environmental issues and just general respect for the earth. They are also an organization that teaches primitive skills and holds an annual rendezvous. Well written and entertaining. Subscription Price is \$10.00 per year.

The Food Insects Newsletter, Florence V. Dunkel, Ph.D., Associate Professor, Editor, Dept. of Entomology, Room 324, Leon Johnson Hall, Montana State University, Bozeman, MT 59717-0302, U.S.A. Phone: (406) 994-5065. FAX: (406) 994-6029.

E-mail: UYFD@MSU.OSCS.MONTANA.EDU

This is the first newsletter I've ever seen dedicated to eating insects! That's right, I said, eating insects. Great newsletter that contains recipes on preparing insects as food like Hot Mealworm Appetizers, Mealworm Cookies, Mealworm Canapes, Marinated Termite Queens, Bee Larvae Dip, Chocolate Covered Crickets, Locust Brochettes. Makes me hungry! They actually sponsor insect tasting feasts for the public. The newsletter comes out March, July and November and costs \$5.00 per year (Back issues: \$1.50).

The Flintknapper's Exchange, 278 W. 8th St., Peru, IN 46970

A clearinghouse for knappers. Bi-monthly newsletter. Subscription Rate: \$12.00 per year.

The Wild Foods Forum, P.O. Box 61413, Virginia Beach, VA 23462

Wonderful bi-monthly newsletter dealing with wild, edible and medicinal plants. Articles, recipes, resources and reviews. Vickie Shufer is the Editor and she and her staff do a great job. You will

definitely want to check this one out. Sample copy: \$2.00. Annual Subscription: \$15.00. International: \$16.50.

TRIBE, P.O. Box 20015, Charlotte, NC 28202, Phone: (704) 827-0723,

Michigan Flintknapperís, Robert Love, 8185 Kiowa Trail, Pinckney, MI  
48169

A group of fIintknappers and primitive technologists that meet  
regularly and hold annual events. They are donation supported. To  
maintain membership you must be actively contributing to the group in  
some way or by contributions, suggested, \$10.00. They have a fine news  
letter for all members and contributors to their group.

The National Association For Interpretation, P.O. Box 1892, Fort  
Collins, CO 80522, Phone: (970) 484-8283, FAX: (970) 484-8179

If you are an educator and/or prehistoric/historic interpreter, NAI

is an organization you may want to be a part of. An organization that provides a medium of communication for American Indian interpretation, environmental education, resource-heritage tourism, Africa-American experience and many others. They also provide services such as a newsletter (NAI News), Annual National Interpreter's Workshop, jobs in interpretation, a guide to suppliers of services and resources, training opportunities, membership directory and much more.

Society of Primitive Technology, P.O. Box 905, Rexburg, ID 83440, Phone Voice/FAX: (208) 359-2400

A network and magazine that is more than a magazine, the Bulletin of Primitive Technology. The most highly technical, yet understandable, magazine on various primitive technologies I have ever read. Contains articles by all the big names in these technologies. Join the Society and order their back issues while you can at \$10 per issue. Free classifieds for members. (\$25.00 year). Subscription price includes Primitive Technology Newsletter.

The World Atlatl Association, Inc., Leni Clubb, P.O. Box 56, Ocotillo, CA 92259

Internet Homepage: <http://users.aol.com/tbprim1/WAA.html>

The World Atlatl Association organizes many events and keeps records of atlatl use, such as distance of spear thrown by atlatl (now over 848 feet!). They also publish a newsletter with archaeological data and modern day accounts of hunts and contests with the atlatl. A great organization and resource for the modern day mammoth hunter. Annual membership dues are \$10.00.

United States Boomerang Association, USBA Membership, c/o Tom Tuckerman, 55 Barrett Rd. #333, Berea, OH 44017

The USBA is a non-profit corporation dedicated to fostering all aspects of the sport of boomeranging: competition, science, art. You are invited to become a part of a growing international sport, to accept the physical and intellectual challenge of the returning boomerang. The boomerang, a stone age tool, with its complex aerodynamics remains relevant in modern times. Membership in the USBA is only \$10 per year and entitles you to 4 issues of Many Happy Returns, the Informative USBA

newsletter, with up-to-date information on competitions, technology, design, personalities, resources, collectibles and more. Also, qualify for entry into tournament thrower rating system. Send checks and money orders made out to USBA.

Mike

Hi neighbor! (I live in Longmont, too)

You could try Cattail Bob Seebeck from Drake, CO for edibles. He did lot of workshops around Boulder County as well as Larmier co. and his fees are very reasonable. His address is:

Cattail Bob  
PO Box 236  
Drake, CO 80515

Sorry, I cant find his phone number.

Tom Riggs

Mike,

Bart and Robin Blankenship know their edible plants and are located near you. Contact them at Earth Knack, Box 19693, Boulder, CO 80308.

I also recommend H.D. Harrington's Edible Native Plants of the Rocky Mountains (ISBN: 0-8263-0343-9).

I've done many timed studies on edible plants. You can contact me directly for information on my own plant book.

Another great resource in your area is the Museum of Natural History in Denver. Make careful notes in the field about the plants you cannot identify. Draw simple sketches and take notes as to the number of sepals, petals, etc., then check out the dioramas at the museum there.

Finally, learn the most poisonous plants first. Be sure you can flawlessly identify water hemlock (*Cicuta* spp.), hemlock (*conium*), and Death Camas (*Zygadenus* spp.) before you start grazing on anything. It is too easy to make plants match a picture in a book if you are wanting to be right. It is similar to making the landscape fit a topographic map when you are really miles off course. Perspective helps. Often when I identify a plant I wait a day or a week before trying it, then ask myself if I am still sure on the identification.

Always Peace,

Thomas J. Elpel  
Hollowtop Outdoor Primitive School

Subject: Growing Wild Rice

Content-Type: text/plain; charset="us-ascii"

X-Mozilla-Status: 0001

Hi all,

Wild rice is not native to Montana, but I have heard of it being grown in ponds here. I have purchased wild rice at the store in the past and thrown it in ponds with no success (a rather expensive experiment!). I am wondering if the seed at the store is viable or not? Would anyone have tips to get me started? Thanks.

Most seeds purchased for consumption will not germinate. The seed companies have hybridized their varieties until only their farms can plant and harvest germinating seeds. If you buy seed corn and plant it, the corn you harvest will not germinate. There are some natural seed companies that may be able to help you. Try herbnet :

<http://www.herbnet.com/university.html>

Maybe others will know more of this.

Thomas,

I can't imagine why it won't work out your way. You certainly don't have temps or winters more extreme than my neck of the woods in Northern WI. One thing I know is that it is very tempermental preferring shallow slow moving streams or shallow lakes or ponds. On a lake north of me where the local Native folks are trying a re-seed project, they needed to drop the artificially high water level (kept that way by a constructed dam), to get it to grow. I have never seen rice growing in water deeper than a foot, and in fact I've never seen it in very small ponds. The rice lakes tend to be fairly good sized, shallow bodies of water. The only source I can think of for information might be the Great Lakes Indian Fish and Wildlife Service. I'll try to get you an address.

It is great stuff! "The food that grows on water" as the Indians say, and the only grass I know of that a war was fought over (the Lakota and the Ojibwa- the Ojibwa won and therefor controled the rice area of WI, MI and MN until European invasion.

Looked into growing wild rice a few years ago in a shallow pond here. Can't put my hand on the exact information I found. What I remember is the seed must be kept wet at all times from seed harvest through shipping to planting. We won't have to go through that process. Found it growing at back of pond this year.

For information on a possible seed source try Native American Food, Nutrition, and Health link to the Lovesick Lake Ladies Cookbook on the Woodland Farm page of our website. This is an Ojibwa reservation and they speak of the wild rice grown there. If they don't sell seed they should be able to guide you to a source.

While the above comment has nothing to do with growing wild rice, it still needs major correction. Hybrid seed from seed companies (or anywhere else) can obviously be planted and grown, and you can plant and grow the seeds that you harvest from it. You will not, however, get the same thing since hybrid seed is the result of crossing specific strains to get certain characteristics, and these crosses have to be done each year to get the seed.

(If you had the parents, you could potentially do this yourself, but it would be a chore).

Open pollinated seeds, on the other hand, breed true and can be saved year to year if not accidentally crossed with another variety. Open pollinated seeds are available from most seed companies.

Please check your facts before posting or take biology 101. (sorry to be so blunt, but that's how I am, nothing personal).

Tom, Being in northern Minnesota, I am surrounded by wild rice, so will offer some help. The product that you buy for eating has been processed specifically to kill the seed embryo so that the grain will store well. You could probably compare it to dry roasted peanuts.

Wild rice is an aquatic plant. It grows in water from one to three feet deep and forms dense stands resembling tall grass. It is an annual and naturally reseeds itself. Upon ripening, the grains fall into the water and a portion of them sprout the following spring. Seed can stay viable under water for up to seven years, thus ensuring a crop even after a bad year.

It can be readily seeded, but you must start with green seed that has not been allowed to dry out. This is usually only available in the fall, during harvest time. There are commercial sources. Check in the classifieds in hunting magazines. There are usually ads on the order of "Attract ducks , plant our natural wildlife foods" or something similar. There are many strains of wild rice, which differ in height, and more importantly, grain size. Here in Minnesota, each lake or river has slightly different rice. Experienced people can tell what lake it came from just by looking at it, and rice from some lakes is highly prized.

A bit of other info on wild rice. It is a highly nutritious food, having a high protein content. After it is harvested, it is usually dried. Then it is parched to further dry the grain and help loosen the hulls (this also kills the seed embryo). Finally it is threshed to remove the hulls. Much

"wild" rice is now commercially grown (mostly in California!). This uses selected strains which tend to ripen more uniformly, the real stuff ripens gradually and the ripe grains fall off of the heads into the water. We generally call the commercial stuff "paddy rice" and don't eat it. (it is better suited to making paste, etc.) If the rice you are purchasing to eat is shiny and black, don't bother. Good natural lake rice that has been properly processed is varying shades of gray to greenish gray to brownish gray. It cooks up fast and fluffy. It is one of my camping staples which cooks up really well in clay pots (like people did it for 2000 years).

If you can't find a source for viable seed rice, or don't want to risk the quality that you might get, I could probably get you some, but not until about the end of August when it ripens. There is an excellent stand of long grain rice about 500 feet from my house which I harvest occasionally. If you are interested in a source for good rice for eating, let me know and I can supply names of some local Native people who have very good rice at reasonable prices (around 5 to 6 bucks or so a pound). This is rice that has been hand harvested and properly processed. Good processing is essential, since much of the commercially available rice has not been done very well (such as the black stuff you usually see).

Hope this helps. If anyone wants more info on wild rice let me know. It is excellent food and stores almost forever. I eat it at least 3 or 4 times a week and always have 100 pounds or so in the pantry.

The best way I know of to carry fire is with mushrooms, the best of which are Fomes, Ganoderma and Inonotus, otherwise known as polypores or shelf fungi. I've carried fire for days and days using Fomes mushrooms to hold the fire. With mushrooms, it doesn't matter if you use a container to carry the fire, or just hold on to the mushroom with a forked stick. It's easy. Gets a lot tougher when you don't have the mushrooms, though, trying to maintain just the right amount of oxygen in a bundle of various materials wrapped tightly. Ben has documented fire

bundles and knows more about them than I do, as many others I'm sure.

Have fun,

Andr 

Barry Keegan is a good friend of mine that wrote an excellent article in our TRIBE newsletter. He is a very skilled survival and wilderness living skills instructor. He wrote the following excellent article on the subject of making strings for bow and drill firemaking sets. I think you all will find it extremely informative. Also if anyone is in the NY area, check out his excellent classes. Information on contacting him follows his article.

-----  
FAST, SURVIVAL BOW DRILL STRINGS

Why Spend Time Fiddling With Your Bow?

By Barry Keegan

©Barry Keegan 1996

WHY BOW DRILL?

The hand drill fire is the fastest means of making fire: if you must start from scratch. I found this to be true in arid environments or seasons of drought. New York State is far from being arid! After years of practicing the hand drill fire I have reached MY physical limitations. I was finally able to make hand drill fires with a spindle and fire board of very dry Mockernut Hickory (our most dense native

wood) but I still couldn't make fire with a damp Mullein stalk spindle on a willow fire board.

Using a bow drill to make fire is more reliable than a hand drill. Because of this climate, damp wood may be all that I have to work with. The problem, though, is finding a good bow drill string that won't take long to make or find! This was a lot of work and lead me to rediscover what can be used.

#### WHY PLANTS?

I limited my self to plant fibers because in a survival situation I can't always rely on animal products to be available for cordage material. For clarity's sake I will rank these bow drill strings in categories beginning with the most year-round available cordage and ending with the most specialized and seasonal ones. Tree bark, branch bark and root bark, roots, wood, stalk fibers, leaf fibers, vines and runners.

#### TREE BARKS

I will begin with tree barks because they are available when the ground is covered by even the deepest of snow. Tree barks also happen to make some of the strongest cords and most of the good ones can be peeled at any time of year. I list tree barks in two categories: Branch barks and Root barks, because each behaves differently and are often handled differently.

#### Branch Barks

"Branch Barks" is the category of bark that comes from any part of the tree that is not a root. However, certain parts of the tree provide far stronger bark than others. Select a shoot or branch that is somewhat straight, preferably with no branches, scars, dead spots or any such flaws that interrupt the bark fibers. The branch should be about three feet long and at least thumb thickness to obtain enough bark for a cord. Avoid very tapered branches. Do pick a healthy branch, dying trees have dying bark and work about as good as they look. Knot holes in bark strings may cause separations that tear out during use. What kind of tree you use is of major importance.

The strongest bow drill string of tree bark fiber in New York also happens to be one of the easiest to make. Mockernut and Pignut Hickory work better than other hickories and are my favorite choices!

#### Peeling Bark

As a general rule, May 1 through August 1 is peeling season: the time of year that bark peels easiest from trees! This is not a long season but farther south it may be longer. The Basswood tree has its own season which starts earlier and ends later than others. Basswood is the easiest to peel at any time of year. There are three methods that I know of to remove bark at any time of year. None of these methods are necessary during peeling season unless you have an unusually difficult branch.

To obtain bark out of "peeling season", you may use pounding, split-separation or if we weren't trying to make a fire, we could use the fire to carefully roast or steam the bark off.

I will begin by discussing the easiest of these methods and end with the most difficult. I will not discuss the roasting method for obvious reasons.

## Peeling In Season

Cut or abrade off your branch of choice and remove any twigs or branchlets, if you have them. On the cut end try to peel the bark free, as if to begin peeling a banana. If it easily separates, and it should, examine the branch for knot holes or areas of removed twigs. You may want to use a sharp stone flake or knife to score the entire length of the branch to make two or three bark strips of even width and as little taper as possible. This is the best way if you did have branchlets on your branch because you can make the cuts align with the branch scars. Holes in your bark strips are less of a problem if they are on the edge of the strip instead of the center.

Careful peeling can produce good results without scoring if you peel both or all three sides at the same time. You need at least two feet of cord from this branch so go slowly and carefully. Watch for sticky spots! Knots can be very sticky. Pull the bark strip at a 35 degree angle or less from its branch to minimize the tapering tear. Pulling straight up (90 degrees) or back on itself (180 degrees) will drastically increase the taper or tear out. Sometimes rocking the strip back and forth as you pull on it can free up the bark at a sticky knot area. If it still sticks, consult the pounding section of this article for another way.

Once in a while I find a branch that won't peel, even in peeling season! Trees can be as different as people are, so, if this happens, find another tree or at least a healthier branch. Peel your bark right away or store the branch completely under water until peeled. Elm bark may not peel the next day after it has been cut. Hickory may not peel after being cut three days before and is noted to stick in times of draught, especially on high hills. On the contrary, Basswood may still peel a month after being cut if it sat in a damp shady place.

As a general rule, the youngest branch or shoot that grew the longest length in the shortest amount of time produces the best bark! Some trees like Aspens will give strong bark only on its one year old growth. Good luck finding long straight Aspen twigs that are big enough to provide enough bark to make a sturdy bow drill string. I had to peel 25 ordinary sized twigs to make mine!

If a branch broke off about two years ago and a bunch of sprouts grew from that wound, there may be enough bark on one of these sprouts to make six bow drill strings. Arrow and basket makers purposely cut back Willows and other plants to force them to grow more suitable shoots for materials. This is called copusing! The deer or a storm may have done some copusing for you. If you know your trees well, i.e. Willows grow by water and deer go there a lot, you may find some choice sprouts growing from a broken "buck-rubbed" branch. Beaver love to eat Aspen!

## Pounding Bark "Out of Season"

If the bark doesn't peel from your branch, find a smooth stone or smooth the bark off of a dead log, this will be your anvil. Then find a sturdy branch of wrist diameter for your pounding mallet. Break it to a one foot length. Scrape your anvil and mallet smooth of any protrusions that may injure the bark that you pound.

Lay the branch across the anvil and begin pounding at the thick end of your branch. Pound till the bark separates on all sides. You need to strike hard, but not so hard that the bark gets crushed. Work down about six inches of the branch's length, pounding every inch or so on at least two of its sides. The bark does separate from the mallet side as well as the anvil side of each blow, if the strike is well centered.

Once you get the feel for how much or little pounding is needed, you can pound the whole branch and then peel it, of course, going slowly to watch for sticky spots. Pound where it sticks till it pulls free easily. If you pull the bark hard past where it sticks you may leave the strongest part of your cord stuck to the branch as the bark tears out thinner.

If it is close to peeling season and the bark sticks, you may score the bark before pounding. Little pounding is needed at this time to remove the bark. In mid winter you will have to pound the bark so hard that it will split where it wants and you will have to choose from what you are left with. At times you may have to pound so hard that the branch becomes splinters! Hickory bark is very tough and can take a lot more beating than other "cordage grade" tree barks.

Hickory and Basswood are the easiest branch barks to remove by pounding because they don't crush easily under the mallet. Gentle mallet work can help remove the bark from Pawpaw, Elm (Slippery and American), Tulip Poplar and Willow. These barks are more delicate! Try working with one to three inch diameter branches because the bark is thicker on bigger growth and can withstand more mallet work. However, pounding becomes ineffective on branches that are more than three inches thick.

You should have no problem obtaining at least one, hopefully two or three, full length bark strips from your branch. Even if the worst happens and your bark as well as your branch are in splinters, save those splinters and keep reading, you can still make a string!

#### Split - Separation In or Out of "Peeling Season"

Once you have learned the split-separation peeling method you may never pound bark again! Now you can peel bark (if you haven't already). This method of peeling may require a lot more practice than pounding but you will be able to peel bark from nearly all of the cordage grade trees at any time of year! Take your thumb-thick branch from a tree or bush by abrading half way through its top side. Then pull down on the branch so it splits and make the split run about two inches down the desired end of the branch. Then abrade the branch off. You need to split the whole branch in half.

Any split-shoot basketry book or article will show you how to do this, but, basically you need to pull with equal pressure and angles on both halves of the split to guide the split down the stick. If one side becomes thicker, pull it at an increased angle to steer the split back to center. This is a faster way to make two equal sized strips without using a stone flake to score the branch. A branch that is thicker than a thumb may be split in three by splitting and pulling on all three splits at once or also split into four by halving the halves.

Remove bark by snapping the split stick near the center very slowly by bending it in both hands, pressing your thumbs on the bark side and bending away so it breaks down to the bark, revealing it. Next bend the break at a 35 degree angle so the wood that clings to the bark peels away from the bark. Then, if you're a righty, hold the branch at the crack, in your left hand so it lays along your left arm down to your elbow and with your right hand, lift and pull away the wood from the bark.

You want the bark to stay flat and taut. Just as if guiding a split, you need to pull on the wood part of the branch so it does all of the bending because it is much thicker than the bark. This should look like a backwards, small letter "y". If the branch cracks or breaks off, peel

up the next section as you did the last, from where it broke off. Keep peeling it like this until all of the wood is removed from that half of the stick.

Then flip the branch around so you are holding the peeled bark in your left hand and the stick part lays along your left arm, as before, and remove the rest of the wood from the bark. With practice this can be done in two or three minutes.

You may lose some bark to splintering on its outer edges. This is less likely to happen if you split the branch into thirds or fourths because the flatter the bark lays on its branch, the easier it is to pull free. Imagine peeling masking tape from a wall compared to peeling it from a pencil which has been covered with a length-wise strip of tape and the edges wrap all of the way around.

Remove the splinters from your bark strips by pulling the bark splinter at a 180 degree angle (back over onto itself). This causes it to intentionally tear out without tearing far at all. Woods that are flexible, like Willows (especially shrubs), will allow you to split a branch in half, third or fourth down along its growth ring(s) so the wood part of the branch is about as thick as the bark is. This makes it easier to separate the bark without breaking the wood part as much. Butternut or White Walnut are too fragile to be pounded but may give strong cordage when peeled in this manner. Even in January it provides a strip whose strength compares to some Hickories. Do remove the outer bark when using Butternut, Mulberry, Osage Orange, Aspen or any bark that won't twist without cracking the outer bark. Outer bark may be removed by scraping with a stone flake or by abrading it off on a gritty rock, but the fastest method leaves you with the strongest results: split-separation! Split the outer bark from the inner bark at one end by using a sharp edge or bend the bark so the outer part snaps away from you. Then peel up a section and split it in half as you would split a branch, by pulling with equal tension and angles on both halves.

#### Root Bark

I will discuss how to dig, find and select roots for cordage later in this article. How many branches are on your root is not as important for root bark as it is for root wood or branch bark strings. Hickory root bark is the strongest of the root barks. It is as strong, if not stronger, than its branch bark and is easier to remove.

Hickory, Walnut, Osage Orange, Red Cedar and some of the Elms and Cherries have root bark that is much stronger than the wood part of their roots. With Mulberry, Black Locust, Willow, American Elm and Hemlock, their root barks and root-wood fibers can be equally as strong. I have found some variations of strength within species and environments.

With the exception of Hickory, the root barks listed above share a unique characteristic unlike any other local plant fiber cordages: elasticity! A root bark bow drill string can stretch up to two inches when pulled tight. Because of its elasticity bow drill strings of root bark do not need to be as thick as those of branch bark. A thumb-thick root is overkill and a pinky-thick root is ideal. For an example of extreme strength I made a fire with a Hemlock tree's root bark string, taken from a root which was half as thick as a pencil. The string itself was as wide as a strand of spaghetti.

To remove root bark, first cut your root and remove its smaller branches. Hang the root over a branch and hold it by both ends as if you were using it to saw the branch. A branch with toothy bark is ideal but

do remove any sharp protrusions that may cut the root or its bark. Buff through the root bark on one side by pulling the root in a back and forth sawing motion. As soon as you've exposed the wood core down the whole root's length, pry the inner root gently out of its bark sheath. Peel the bark from the root at the same 35 degree angle that you would to remove tree bark.

Root bark peels easiest in bark peeling season. It peels almost as easily when out of season! You do not need to pound roots to remove their bark. Split-separation does work on roots but it's not necessary. Walnut is one of the few root barks that needs to be separated from its brittle outer bark. Most of the root barks listed here may be used "as is" for bow drill strings. Root bark is a better choice than branch bark when it's available.

Ok, ok. I'll let the Tom Brown thing drop.

Having had no instruction but having read a description of fire making with a bow drill, I decided to try it. Pine (I had read) was not a good choice, but it was handy so I used it. I used maple for the hand piece. To my astonishment, I had a fire going in 5 minutes (after spending 1 1/2 hr. making the thing). I decided I had an uncanny natural ability, and gathered the neighbor kids to demonstrate my skills. With the same apparatus, I went to work, and after 15 minutes was soaked with sweat, and had only smoke and light brown crumbs. The kids got bored and drifted away one-by-one shaking their heads.

I think the end of the spindle and the fire board became fire hardened in the process and prevented a coal from forming. The thing screamed something awful too while it was spinning. I'm going to try other woods, but I wonder if anyone else has had similar problems.

Mark,

Good work with the firebow! Getting a fire started the first time is often the biggest challenge..... failing on the second try is the master bummer and from our experience, quite common.

There are a lot of possible reasons for.....

> The thing screamed  
>something awful too while it was spinning. I'm going to try other woods,  
>but I wonder if anyone else has had similar problems.

The most probable in my opinion is that the drill and the fire board were binding. We suggest that after each attempt at starting the fire, you abrade or carve facets into the tip of the drill. At the same time sharpen the bearing end of the drill to reduce friction in your hand bearing. We lubricate the bearing end of the drill with oil from around the nose area (just rub the tip into the crease around your nose) or the hair. My favorite is ear wax harvested for the purpose of lubricating the drill. Do not use water, water will cause the drill to expand and bind.

As a bearing, for folks learning the technique, a well taped (use duct tape and LOTS of it, on the outside of the glass, natch) shot glass is great. The drill spins with very little effort. The glass could break and that is why it is taped. My favorite bearing is a flattish, pecked hole, stream stone. I've been using it for years. Other good bearings are antler, bone (vertebrae work nicely) and if you have access to it, Manzanita works fairly well. There are lots of other things that work but reducing friction in the bearing is of great importance.

The drill can be made of many woods. We recommend "Squaring" the drill to make flat areas that will engage the cord like a gear. The cord works best if it is "double twisted" as in cordage construction. This results in a "Bumpy" cord that will engage the flat areas and high points of the drill. The drill will spin even under heavy pressure. A double twisted cord will last much longer, this is particularly true if you use parachute cord or shoe laces.

At the fire board end of the apparatus, if your drill penetrates too deeply into the board, start a new hole or reduce the diameter of the drill to eliminate binding between the drill and board.

After teaching the technique to several thousand folks, I've noticed that the rythmn of the arm is one of the most important learned skills. The drill should be fairly stationary when you move the bow. Take long smooth strokes with the bow so you use as much of the cord as possible with each stroke.

When you are practicing the skill, try using four zero (0000) steel wool to catch your spark. When you get the spark you can blow it inot flame easily.

There's much more to add and there are lots of experienced folks here to add it.

Good luck and happy strokin'

Ron Hood

Mark, I also have gotten fire with pine, although, what I used was punky  
lodgpole and not the white or red that grows heavily in my area. The  
pitch content was problematic as it caused several problems:

- glazing (accounting for the screeching sound you encountered)
- continuous binding that could not be easily elivated by  
methods I normally use
- a powder that tended to clump up necessitating a redesign of  
the notch.

While the experience taught me that I could indeed use pine in a pinch,  
given a choice I would use much harder woods like birch or maple before  
I would try pine in an emergency.

> I'm going to try other woods,

I would recommend it. Pine is not a good wood to learn on. I'm not sure  
where you live but try alder, cottonwood, willow or Eastern White Cedar  
first and get good with those before tackling the rougher stuff.

My favorite is the astragalus bone (from the rear ankle, or hock) of a deer.  
It fits nicely in the hand, has a good socket, and comes with its own grease  
(if you don't over-clean it).

Sound great! I'm going to keep my eyes peeled for a deer carcass! (might give me the excuse to "brave" some maggots at the same time)

What I'm using for "a quick" socket

>From Mor Kochanski's book he suggests the thick bark from Balsam Poplar (I believe down east they call them "Bamagillian" (sp?) or something).

Anyway that's just about all I use (I know bad habit, in case there is none around when I find myself in a "situation") But it's readily available, and you can fabricate a socket in 30 seconds! The secret is in the woods (barks) softness. It has the consistency of balsa wood and when your spindle starts to "drill" the resulting powder is like graphite! Granted it wears out fast, but one hand size chunk can make several fires, and supposedly this same dry bark thinly shaved into "wool" will actually suffice as tinder for the ember (I will try this) Is anyone else out there using this also?

I think you've run into the "didn't hold your mouth right" problem. This seems to be not an uncommon experience. Keep practicing and it will become second nature.

My favorite woods are aspen or cottonwood for a base board and yucca flower stalk, aspen or cottonwood (in that order) for a spindle. Years ago I found a "knuckle" bone from a old dead cow that has proved to be a great hand socket. It has a hole in one side that fits the size of spindles that I use( 1/2" to 5/8") very well.

I find that pine has to much pitch in it. It will work, but boy, do you have to work.

There have been some excellent articles on friction fires (bow drill & hand drill) in the Bulletin of Primitive Technology that is published by the Society of Primitive Technology (SPT). Cost is \$25 yr for two issues. \$25 may seem like a lot, but the info on all aspects of the subject are more than worth it. Contact the SPT at P.O. Box 905, Rexburg, ID 83440. phone is 208-359-2400.

I apologise for the commercial, but I think you'll find a gold mine of ideas.

Keep on makin' smoke! FP

Whether fire by friction is by bowdrill, handdrill, fire saw or fire thong, the theoretical principle of what makes this work is very useful to know. I will try to put words on something that anyone who has practised these skills for a long time tends to know by "feeling".

When wood is rubbed against wood, one of the materials is harder than the other. Even when the wood for fireboard and spindle are of the same wood, the spindle is harder than the fireboard in the sense that the fibers are cross grain rather than with the grain. Thus, basic theoretical principle #1, the harder wood grinds wood dust from the softer wood. Of course, some wood is ground from the harder of the two wood pieces too, but much more from the softer of the two, in this case the fireboard. Principle #2, is that when wood grinds hard enough, wood dust is created in the form of sawdust. Principle #3, when wood grinds hard enough and/or fast enough, heat is generated and the sawdust starts smoking and charring.

Now, the following is very important. Usually, sawdust is light, and when you rub wood, the sawdust moves away from the friction area and

thus cools off, and new wood is rubbed which creates new sawdust which is cooler. This means that theoretically, you can do this forever and never obtain a coal or a fire.

Principle #4, then, is that to obtain a coal, YOU MUST RUB WOOD OVER AND OVER ON THE SAME SAWDUST. This is why you cut a notch in the fireboard, for instance. The hot sawdust gets wedged in the notch, preventing it from moving away from the friction area, and you are then rubbing over and over on the same sawdust and a coal will get created at that exact spot.

The coal then spreads to the remaining sawdust, making it grow, creating sufficient heat to flame tinder.

Principle #5, weight. Ususally it is not sufficient to have the burnt sawdust wedged in between a crack. There is also a weight consideration. The pile of sawdust must be big enough and therefore heavy enough to prevent the newly formed sawdust from moving it and cooling it off.

The 6th principle deals with the fact that for fire to occur, there must be sufficient combustible material. If there is not enough wood sawdust around the forming coal, it will not gather the momentum necessary to grow to usable size. Just like a fire can't be built with a match and a single stick, a coal cannot form if there isn't enough burnt sawdust around it.

Finally, 7th principle, a fire needs air to complete the heat-combustible material-oxygen trio necessary for ignition. This is much less important in practice because the small wood sawdust balls under a microscope reveal plenty of air space between them.

Now we can look at practical questions. Can a bowdrill fire be made without a notch? Yes, it makes sense now, doesn't it? Just keep drilling long enough and hard enough so that the burnt wood sawdust pile around the friction area gets big and heavy enough not to move as you keep drilling. I have obtained up to 5 coals at once all around the drilling area this way.

What about the fire saw. Well, as the saw traverses the bamboo half round board, burnt wood dust accumulates underneath and you are rubbing back and forth on the same pile of wood dust which can't move because it's stuck underneath the board! As in bow drill and hand drill, it is now obvious (or should be) that filling the notch with tinder will prevent a coal from forming...

Fire thong works on exactly the same principle. The thong goes underneath a piece of wood which is split open about 1/4 inch, and burnt wood sawdust accumulates above the thong and gets wedged in that split and can't move. Once the crack is full, the thong rubs back and forth against the same wood powder and the coal ignites there.

The fireplow technique is harder to understand and doesn't work everytime because it relies on brute strength to generate sufficient heat in the pile of wood dust to ignite a coal at a random spot in the pile. Since this technique cannot be duplicated precisely the same way everytime, it is hard to come to a conclusion about what is happening

but I think it is this. As the pile of wooddust at the bottom of the plow gets heavy enough and cannot move, the heat transfer from the friction area ignites a coal on the bottom edge of the pile, which usually manifests itself as a coal on top of the pile when it is accidentally hit by the grinding stick. Note that I have tried making artificial fireplows by tying sticks to my jigsaw blade and was not able to produce fire! The principles are not respected accurately in this technique, and probably a random crack between the dust pile and the plow board must permit the formation of the coal. Scratch me!

As for the new "fire hole" technique, there must be a crack in one of the pieces of wood in which burnt wood dust can accumulate. It will most probably look like an upside down fire saw. Can't get away from the principles if it is to work. Looking forward to Ben's post on this.

Hope this helps...

Andr=E9

I live in near the Seattle area and as you have probably heard it rains  
allot here. Finding dry wood in the wilderness can be some what of a chor=  
e  
at times. I have found that gathering different types of wood require  
different techniques. Some of the woods listed are good in an immediate

survival situation others require preparation and aging. As you probably already know the native inhabitants use to spend the summer months curing and building their fire making tools. So not all of the wood types I use = to make my fire board and spindles out of can be utilized in a emergency survival situation. The following two list of techniques I use to gather = my wood during the wet season which around here is about nine months a year.

Requires Aging:

Birch and Willow:

Birch and Willow make good bow-drill materials but I live high up in the mountains and these trees generally grow in the lower wetlands and around permanent water sources. They are very rare where I live but I can find them about 30 kilometers away from me. I have only used them with a single fire board and spindle set and got good results from them. But I have not used them enough to gain any expertise in there use. Some other people on the Trackers alias have used these wood types quite often and could probably provide more information about them. I happen to be very fond of the Paper Birch because its flaking bark is the best natural fire starter= I have ever found. When I come across one of these trees I always collect the outer bark for future use.

Cedar, White and Red:

I have never found any cedar that I could just pick up and use. Cedar tends to be either rotten or has absorbed lots of water so I have always had to cure this wood before I use it. I like Cedar because for me it has always proved to make good fire boards. In my experience Cedar fire boards can be used with various other spindle wood types with good results. Somebody once told me not to mix fire board and spindle wood types. I did not listen to them and tried it out for myself. I have had many successes and many failures, the key is to figure out which combinations work well together.= A Cedar fire board will work with almost any other spindle wood type. This is where the value of this wood type comes in, you cannot always be guaranteed to have the same wood types for your fire board and spindle.

Gather and Use:

Alder:

Alder could be in either category but around here during late fall we get high winds that help me in the wood gathering process. Alder trees around here tend to split down the trunk or large branches brake off during the high winds. Sometimes these branches become large snags and can be collected during the summer months a year or two later when the wood has sufficiently cured. Gathering these snags require some climbing and as yo=

u  
probably know climbing a mature Alder is not that easy. This is where I g=  
et  
all of my Alder from. The pieces that hit the ground get collected cut up  
and cured for a year and used for practice pieces. I found second growth  
forest's about thirty to fifty years old are good places for gathering  
Alder.

#### Douglas Fir and Grand Fir:

Finding Douglas Fir and Grand Fir are the some of the easier dry wood typ=  
es  
to find. Douglas Fir and Grand Fir are very abundant around here and due =  
to  
the natural aging of the tree the lower branches die and become very dry  
inside after a year or two, assuming the bark has remained on the branch .  
To retrieve the branches you can climb the trunk and break them off. The  
way I prefer is to take a large throwing stick one with sufficient mass,  
and throw them at the old dead branches until they break off. These two  
types of wood make good spindles, but they don't last very long due to th=  
e  
loose grain of the wood. This loose grain makes them great for generating  
generous amounts of coal dust with minimal effort.=20

#### Hemlock:

Finding Hemlock in my area is also quite easy, but this wood is very  
unusual and requires lots of practice to use as bow-drill material. The  
best result I have had gathering Hemlock is to collect fallen branches on  
rocky hillsides. This keeps the wood off the wet ground and allows it to  
dry out quicker. This wood makes very long lasting spindles due to the  
dense grain. Carving a straight branch into a spindle is quite a chore du=  
e  
to the unusual characteristics of this wood. I have at many times picked =  
up  
a Hemlock branch which has been laying on the forest floor for at least a  
year, just shave the bark off carve the ends and use it right then and  
there as a spindle. Using both spindle and fire board made out of Hemlock  
is futile. You will twist your arm off and get nothing but brown dust. I  
only recommend using this wood as a spindle and always use a softer wood  
such as Cedar or Douglas Fir for your fire board.

Do you have any information about using Mountain Ash for bow-drill  
materials. These trees can be found every so often where I live. I have  
never tried them due to my belief in only using dead wood in non-survival  
situations. I personally prize these trees due to their berries which ten=  
d  
to stay on the tree throughout the winter providing a nice trail side  
snack. Although they don't taste very good in the summer after the first  
freeze of winter they tend to be transformed into a fairly palatable food  
source.

I have sent the following GIF and JPG image file attachments so you can  
make sense of the notch types.

Notch 1: Mediocre

Notch 2: Fair

Andr=E9,

Sorry I have not written back promptly I have distracted for the last week.

I tried getting signed-up on the Primitive-Skills-Group from your webpage

but I have never received any mail yet. Well your where asking what my preference of wood types for immediate survival use. First I must add that

preferences are based on my geographic location in the Pacific North West and are particular to the amount of moisture this area receives. The main reason I choose these types of wood they can be readily found already cured by nature.

#### 1. Douglas Fir

I like Douglas Fir the most because I can always find dry dead branches on the trees. The wood is soft enough to carve or split quickly in a need it now survival situation. I can always find this wood type in my area no matter where I go.

#### 2. Alder

I like Alder a little better than Douglas Fir for making a fire but it comes in second due to the difficulties finding dry non-green materials during the wet season.

#### 3. Grand Fir

Grand Fir can have allot of pitch in it at times. This can be a major problem collecting the right piece of wood for your set. It is not one of my favorites but I have used it before.

#### 4. Hemlock

Hemlock I use but would not recommend unless it is all you have to use. The way the hemlock grows around here the rings are usually to dense inside the branches to make good spindles out of. This wood type requires a well practiced technique to use this type wood. Hemlock is not very suitable for fireboards

Cedar is my hands down favorite for making fireboards but I have never found any pieces I could collect and use right on the spot. Cedar for me = at least has always required curing and that won't help you out in a survival situation. The problem with making a list like this is there is no one perfect material. It always depends on the geographic location, weather patterns. I have found the same species of trees growing in different parts of the continent have totally different growth patterns and characteristics. This makes it hard to nail wood types down into a science for what would work the best. There is also the issue of a individuals skill and technique using the bow-drill. I have seen people the can start a fire with Oak. I don't imagine they would be able to do it with natural cordage strung to their bow.

This post is from Mark Besse who has now joined our group (WELCOME  
MARK!), thought some of you might like it- Andr 

-----  
Well due to some =  
requests I will try to explain the different notch types with words. I =  
don't know if I can explain the different notch types with the same =  
impact that a picture would, but I will try.

Notch 1: The notch type is a 1/8 pie V-wedge. This is the basic notch =  
type taught in Tom's Standard Class.

Notch 2: The notch type is a 1/6 pie V-wedge. This is basic notch just =  
widened a little bit.

Notch 3: The notch type is a 1/6 pie V-wedge. This one differs from the =  
previous two due to the placement of the spindle groove. The spindle =  
groove is placed further from the edge of the fire board. This allows =  
more dust to collect in the notch without any spill over, thus =  
generating a bigger coal.

Notch 4: The notch type is a 1/6 pie lobed U-wedge. This shares it's =  
spindle groove placement with notch #3. The only way I can describe this =  
notch is it really looks like the shape of a "U". You start creating =  
this notch by creating the standard V-wedge. Then you start =  
straightening the sides and rounding the bottom off. Like the V-wedge =  
don't cut all the way to the center point of the spindle groove. That's =  
it!!!

The reason I believe this notch works better are listed below.

1. The notch has sufficiently more surface area than the V-wedge.
2. The notch allows more dust to collect closest to the source friction.
3. The notch allows more oxygen to feed the dust during coal generation.
4. The natural curve at the base of the notch is less traumatic on the =  
new born coal when removing the fireboard.

They say that "Necessity is the Mother of all Invention", so here is a =  
little story. I live in Washington state and during the wet months which =  
is pretty much all of the time finding good tinder around here is pretty =

dammed difficult at times. So I experimented with the idea of starting =  
fires without a tinder. I had been saving extra coal dust after each =  
fire and I decided to use it somehow. I found once you generate a coal =  
and you keep adding new dust to it slowly, you can grow a coal into the  
=  
size of a golfball. By adding new kindling to this huge coal you can =  
easily start a fire without a tinder. This notch configuration came from  
=  
my desire to make really big coals.

Here are some embedded image files for those who's e-mail can deal with  
=  
it.

I have found that notch geometry is critical. I have developed a system that automatically scales the notch to the board and drill (Don't laugh, I have an engineering background and the method seems overly technical. But once you try it, it works itself.) All marking can be done with your knife. For simplicity, lets assume the fireboard is rectangular with rather short ends and rather long sides, but the technique works with other shapes.

1. I like to use a drill that is approximately the diameter of my little finger and a board the thickness equal to the width of the nail of my little finger.
2. Start by placing the prepared drill end at the edge of the fireboard somewhere along its length. Place a mark on the other side of the drill so that the mark is one drill diameter from the side edge. This distance will probably be shorter than from the mark to the other edge of the board. All subsequent marks and notch cuts will be made in this shorter area. Note: when using mullien or teasel it is a good idea to scrape the crusty outer skin off the end that contacts the board.
3. Press the drill into the board to make a circular imprint (the fireboard wood should be soft enough to indent when pressed with your fingernail, I like willow or basswood). Use you knife to dig a shallow disk shaped impression.
4. Place the drill in the impression and twirl to burn in a ring shaped hole no more than 1/8 inch deep. This assumes you have a hollow type drill material, but I have used the technique successfully with a solid willow hand drill.
5. With your knife, scribe a line all the way around the board, tangent to the burn ring and parallel to the short ends of the board. This is line 1. (later, once you see how this all works, you will only have to go half way around)
6. Scribe another line the same way on the other side of the ring. You now have two parallel lines on each side of the ring. This is line 2.
7. Scribe a third line around the board, passing through the center of the ring. You now have three parallel lines. This is line 3.
8. Use your knife blade to measure the distance from the nearest side edge of the board to the center of the ring. Turn the board over and place a mark this distance from the same edge on the bottom of the board. This mark is now under the center of the ring on the other side, and intersects the middle scribed line. Let's call this point A.
9. Scribe a line from point A to the intersection of line 1 and the bottom edge of the board. This intersection is point B.
10. Scribe a line from point B, up the thickness of the board to the top of the board and on to the intersection of line 3 and the nearest edge of the ring. This intersection is point C. The line should be the shortest distance from point B to point C. If you look from the edge of the board toward the ring, the line will look diagonal about 45 degrees as it runs from B to C.
11. Scribe a line from point A to the intersection of line 2 and the bottom edge of the board. This is point D.
12. Scribe a line from point D, up the thickness of the board to the top of

the board and on to point C. If you look at the board from the edge, you will see that you have now scribed a diamond shaped figure wrapping from the bottom to the top of the board. The first time it may help you to visualize this by coloring in the diamond with a pencil.

13. With your knife, chop out a small wedge of wood from the bottom edge of the board into the center of the diamond (just two straight v-cuts). Make the wedge bigger until it expands to the form of the diamond. You will now have a notch that flares down and out as described in some books but scaled precisely for your materials. Make the notch extend into the burn ring at point C until you hit the inner, unburned diameter of the ring.

Now the notch is complete and you can insert the drill and try for the coal. As the drill burns into the board, an ever widening hole forms into the notched out area. The geometry of the notch compacts the dust and reflects the heat toward the center of the dust pile.

This explanation will seem hopelessly complicated unless you do it as you read. Even then it may be confusing without a drawing. Let me know. I have been very successful teaching others to do it by example but this is my first attempt at a description. I would like to hear your comments.

Phil Goetz wrote:

>=20

> > use a rounder bow which permits squeezing the string more.

>=20

> What does this mean?

Now we're getting into bowdrill biomechanics which are a little hard to=20  
explain through this medium. I'll try to give you an idea, but I will=20  
be publishing an article on this shortly and will let you know more=20  
details.

Basically, the standard way of making a bow is with a fairly straight=20  
piece of wood. When the string starts slipping, your only choice is=20  
either to retighten the string or to push away with your thumb to=20  
tighten the string somewhat. Biomechanically, this is quite inefficient.

I developed a bow drill method using a saw shaped bow which is straight=20  
on the handle and then curves back. Like this, only rounder:

This is made in the forest in several ways.

1. Find a natural curved one like this, usually at the base of alders=20  
(*Alnus* spp.) on the edge of creeks.
2. Find an L-shaped branch and use it, usually from poplar (*Populus*=20  
spp.) trees which have a tendency to this shape.
3. Use a straight branch and shave it beyond the handle so it bends to=20  
the correct shape.

When you use this bow, which is best if it is quite rigid, you can then=20  
start with a loose string, and PULL on it using three fingers for=20  
perfect control of tension. This is also useful once you have the coal,=20  
because by simply releasing the string, you can remove the spindle=20  
without it jumping out because of the lack of tension on the bow.

Pulling with three fingers is infinitely stronger than pushing away with=20  
one thumb, but more importantly, you can also biomechanically generate=20  
much more global force with this method because you are using the biceps=20  
instead of the shoulder muscle, which is much stronger. Another reason=20  
this is more efficient is because of the shape of the bow permits=20  
maintaining your wrist in a straight position which means again more=20  
biomechanical strength.

To give you an idea of the way to hold the bow, pretend it was a saw=20

where the string is the blade, and when in position, "saw off" your left=20 ankle as you drill with the right arm.

I hope this is clear enough so you can try it. Let me know what you=20 think of this. Please note that I developed this myself because I had=20 no teacher while I was learning this skill, and maybe my judgment of=20 it's efficacy is overestimated. I would love to have your opinion after=20 you have given it a fair chance.

Good luck,

Andr=E9

> your calculations tell you should work.

On this one I have to agree in part with both of you. In my experience, Eugene's idea works- you do get more speed by narrowing the spindle diameter while leaving the bottom larger. However, in practice Mark is right- this advantage is often offset by the new problems of slipping strings, weaker spindles, and more bottom-end friction. But if these disadvantages can be solved, then the advantages are all that remain.

For me, scientific theory is always the basis for practical experimentation. I have never had it fail me. It's just that sometimes other factors which the theory did not account for have not yet been considered.

Ways I have found to offset the slipping string problem are: wrapping the string twice around the spindle, use a rougher string (double-twisted), make the spindle octagonal in cross-section instead of round, and use a rounder bow which permits squeezing the string more. When this is done, the advantages of speed of a smaller diameter spindle do make a difference with difficult woods.

Peace,

Andr=E9

> What was the diameter of the first spindle you used before the 1 1/8 then  
> 5/8"? Also, what cordage are you using, nylon?

The first (damp) one was only about 1/2" in diameter. My cordage is  
synthetic (braided nylon), and I reverse twisted it so it would be a little  
bumpy, as Ron Hood suggested.

Mark I hope this helps I will try to explain the technique for generating a good coal. There are two basic stokes involved to generating a good coal.

The dust building stroke:

The concept of the dust building stroke is to generate enough dust to build a coal out of. Start out with mild downward pressure on the bearing block. Make slow and even stokes with the bow so that spindle ends up bottoming out at the far ends of the bow. Many times when teaching others I have found they tend to make very short strokes, make your stoke long and smooth. This is a very casual stroke so take your time and try to conserve your energy. Don't try to generate smoke with this stroke at first you are more interested in generating dust. At the end of this stroke you should start to increase the pressure on the bearing block and smoke should be coming from the notch. Now you should transition to the next stroke.

The coal building stroke:

The concept of the coal building stroke is to generate enough heat to build a coal. Start increasing the bow speed and then downward pressure on the bearing block in a linear fashion. This is the most important stroke for generating a stable and viable coal. The more speed and pressure you can apply the better. It is very important to remember that there is linear relationship to this speed and pressure. The speed of the bow dictates the pressure you can apply to the bearing block. If you apply too much pressure and not enough speed the spindle becomes unstable. On average for me this stroke lasts only about fifteen seconds. I have found that when teaching my friends that they tend to use their arm strength to apply the downward pressure on the bearing block, this drastically affects their endurance. It is very important to use proper technique, let your own upper body weight do the work. This is hard to explain but I will give it a go. The arm that is holding the bearing block should be locked firmly against the leg that is securing the fireboard. To apply more pressure to the bearing block simply shift more upper body weight over the spindle. Transfer your upper body weight through the arm holding the bearing block. The only strength required on this side of the body is being used to stabilize the bearing block against the leg. The downward pressure should only be coming from your own upper body weight.

One of the hardest parts of this task is knowing when you have generated a sufficient coal and you can stop. I have my own personal technique I use, and it is really difficult to explain without seeing it first hand. I will try the best I can at explaining this one. During the coal building stroke watch the smoke carefully there are different types of smoke plumes that come out of the notch. The early smoke plumes tend to stream straight up. When the coal is ripe and ready for picking I have noticed the multiple smoke plumes tend to bulge out from the base of the notch in a circular fashion. It is almost like miniature mushroom clouds chasing each other out of the notch. I know this is a difficult description but I tried, if you watch the smoke carefully you might see what I am talking about.

Redwood does not work well for a spindle and fireboard it has natural fire  
inhibiting properties to the wood. It sounds like it might have been Red  
Cedar

which is very fibrous and tends to get chewed up pretty quick. A special  
technique is required to use Red Cedar.

Well, I don't know whether I got unsubscribed, or there really has been a  
steep drop-off in posts, so I thought I'd send in an up-date on my personal  
attempts at bowdrill fire making to see if anyone is listening.

I posted previously about using pine with initial success and subsequent

failure. I got some good advice from this group, and located some downed White Birch from my neighbor's brush pile. I made both the fire board and spindle from this wood. The first spindle was a bit damp, and all I got for my trouble was some smoke. I read from someone's post that it is possible to dry the wood enough to get fire just by heating it in use. Maybe I was too easily discouraged, but I could not get a coal with this wood.

I then made a spindle from dry Birch about 1 1/8 " in diameter. With this I was able to get a coal pretty quickly, which I dropped into a nest of 4-0 steel wool blew into a flame. (I get so excited every time this happens.) I then made the spindle 5/8" in diameter and repeated the process. I think it went even quicker with this smaller spindle. The Birch seemed pretty hard, and I was surprised that it worked so well.

Rummaging through my garage, I found an old piece of Redwood (I think) for a spindle and fir for the fireboard. The spindle was very soft wood, and I was impressed that it produced dust and lots of smoke quickly, but seemed slow to get hot enough to get a coal. I finally did get fire, but I was pretty worn out.

I looked at Marc Besse's post about the shape of the notch, and experimented with the shapes he described. I found (as he suggested) that the U-shaped notch was the most efficient. I have found that I have to cut the apex of the notch quite short of the center of the depression in the fire board or the drill migrates toward the notch too far.

I have never yet been able to let the coal sit in the notch for 1 to 1 1/2 minutes and fan it until it glows red as I have seen suggested. The best I have done is get it to smoke for few seconds, and if I don't then transfer it to the tinder bundle, it goes out. Maybe I need to spin the drill a little longer to get more heat, but by that time, I'm usually out of gas.

Just trying to stay in the conversation.

I agree with this very much. This does not need to be a struggle. Use  
the whole bow, and I have also found that pointing the tip at the ground  
can help beginners maintain the string in the center of the spindle and  
thus avoid the see-saw motion that causes the string to ride up and  
down.

> The coal building stroke:

> The concept of the coal building stroke is to generate enough heat to

I'm not sure I necessarily agree with the whole concept of speed being important. Like I mentioned earlier, a thinner spindle allows you greater speed with less effort. I simply do not crank away like crazy anymore. There just isn't a need. I believe that downward pressure, though, is critical and the body position you describe is important. Technique, is the single most important factor in fire making aside from correct construction and the notch.

As to when you know whether you have a coal or not, this is a bit more difficult. I was first taught to wait until the smoke swirled around the spindle and then add 10-20 more hard strokes. This doesn't seem to apply, and I just don't do the "hard stroke" thing anymore. Charles Worsham speaks of building the powder to the bottom of the depression in the fire board and waiting till smoke comes out the back of the coal in the notch. This actually seems to have more merit. Sometimes I simply just know that I'm there. The more you work with the tool, the more this will happen. However it happens, a good coal will sit and burn on its own for a good 10 or 15 minutes and I usually have fairly big coals.

> It is very important to remember that there is linear  
> relationship to this speed and pressure. The speed of the bow dictates  
> the pressure you can apply to the bearing block. If you apply too much  
> pressure and not enough speed the spindle becomes unstable.

I'm not sure I agree with this either. Technique and body position, again, are the key things. I can add a lot of downward pressure and still maintain a nice even, slow stroke with the bow. I don't think it has to be a fight. I'm sure my spindle diameter has something to do with this.

I have found that when teaching my  
> friends that they tend to use their arm strength to apply the downward  
> pressure on the bearing block, this drastically affects their  
> endurance.

This is certainly true. The whole upper body needs to be used to get good downward pressure. It also helps to make sure that the alignment is correct. The front shin should be perpendicular to the ground and the center of the chest should line up with the center of the hand locked around the shin, which in turn lines up with a point about an inch away from the center of your instep (the hole in your board should be at this point). This allows you to keep everything locked in tight and still have the spindle straight up and down. Physical strength is not necessarily a crucial factor here. Good technique can make up for a lot of things. I like to relate this to martial arts in this sense. A powerful karate technique does not depend on muscle power, in fact muscle power can get in the way often. The key to a powerful punch is technique and connection, balance and relaxation with controlled tension. Starting a fire with a bowdrill is very similar :-).

My success with damp wood has been by reheating the powder until it dries and ignites.

Well, you seem to be discovering things by trial and error. 5/8-1 1/8" spindles are awful big. No wonder you are winded afterwards! It is easier with smaller diameter spindles (smaller diameter increases the rpms). According to Charles Worsham, the harder your wood is, the smaller the spindle diameter too, but I would argue that with softer woods like cedar, basswood, alder etc. there is a point at which small diameter can become a problem. Right now my cedar spindles are about 1/2". That seems to work well for me. If I go much smaller than that I seem to burn through the board before I get a coal, any larger than that means that I do more work than I need to. Birch is definitely harder than most woods I prefer. Try a 3/8" or smaller birch spindle and see what happens.

I've never tried this combination. What did the coal look like?  
Fibrous? Plate like? Dark, fine powder?

One thing that I am working on now is perfecting my form and kits to the point where making a fire is a slow, almost leisurly activity. It does not have to be a struggle that leaves you out of breath etc. The key is adjusting spindle diameter, fireboard thickness etc. to fit the different woods and positioning and using your body in a way that uses maximum efficiency for both downward pressure and bow manipulation. I like the idea of looking at this stuff as an art rather than just a form of exersize. If got enough of those :-)

This is true but the tradeoff is the speed of the spindle rotation which increases towards the edge of the spindle (see follow up below).

>woods like cedar, basswood, alder etc. there is a point at which small  
>diameter can become a problem. Right now my cedar spindles are about  
>1/2". That seems to work well for me. If I go much smaller than that I  
>seem to burn through the board before I get a coal, any larger than that  
>means that I do more work than I need to.

A technique employing mechanical efficiency would be to use a larger spindle for the softer woods but shave the spindle diameter down in the center of the spindle where the cord makes contact. This gets you speed from applying the force of rotation nearer to the centerline of the spindle, but keeps the spindle rotating faster at the edge (the edge is where the action is). Every unit of radius differential changes the outside edge by a factor of pi (3.1415927...). And remember.....the

techniques don't make you work, you make the techniques work.

In a message dated 97-02-04 13:34:25 EST, you write:

<< I then made a spindle from dry Birch about 1 1/8 " in diameter. With this

I was able to get a coal pretty quickly, which I dropped into a nest of 4-0 steel wool blew into a flame. (I get so excited every time this happens.)

I then made the spindle 5/8" in diameter and repeated the process. I think it went even quicker with this smaller spindle. The Birch seemed pretty hard, and I was surprised that it worked so well.

>>

Yes the server is still workng. Must be a lot more off-server corresp going on. Thanks for keeping it up.

What was the diameter of the first spindle you used before the 1 1/8 then 5/8"? Also, what cordage are you using, nylon?

i agree on the yucca, i've gotten a bunch of fires out of my BSA set. I did however, replace the bow and string with one of my own making.

This is my first post so I'll introduce myself. My name is Bill Qualls. I am an assistant professor of mathematics at Waubonsee Community College in Sugar Grove, Illinois. My survival experience includes three 3-week courses at BYU in 1976 (once as a student, twice as instructor), a lecture course with "Rabid Ron Hood" at UCLA in 1978, and Boulder Outdoor Survival School's two-week field course in 1995.

There's been some discussion about teaching fire by friction.... I have taught fire-by-friction to probably 100+ scouts. And I don't mean demonstrating it: I mean each of them getting a fire. When it comes to teaching fire by friction, I don't think you can beat the official BSA fire by friction set. The materials - yucca - are perfect. Sure, they should learn to make their own set, but for getting the "feel" of making the fire, and for the confidence in their abilities to do so, you can't beat this set. It's pricey (approx \$8??) but before I knew how to do it, I would gladly paid that much to know how. I usually find that 3-4 kids can get their first fire from one set.

Also, had an old time scouter recommend to me once that for the socket, try using an old glass coffee percolator top. No friction at all!

Ben Pressley suggested I "clean-up" my original post on the above=20 subject for publication in the Tribe newsletter. I went a little=20 overboard and produced the following document. Hope you enjoy it. =20

Andr=E9

PS Ben, hope you don't mind that the members of the group get to see it=20 first... it's all in the family!

-----  
FIRE BY FRICTION THEORY  
-----

INTRODUCTION:

Whether you wish to obtain fire-by-friction by bowdrill, handdrill, fire=20 saw, fire thong or fire plow, it is most useful to study the theoretical=20 principles underlying the processes involved. In this brief and=20 informal article, I will address the issue of how the coal actually=20 forms. I will attempt to put into words something which anyone who has=20 practised these skills for a long time tends to know by "feeling". =20

THEORY:

=20

GENERAL THEORETICAL PRINCIPLE- FIRE IS OBTAINED WHEN THERE IS ENOUGH=20 HEAT (IN THE PRESENCE OF OXYGEN) TO BRING FUEL TEMPERATURE TO IT'S=20 IGNITION POINT.

Let us examine each of the three well-known fire elements=20 (heat-fuel-oxygen ) in the context of fire-by-friction. Basically, heat=20 will come from the friction of wood (or woody plants), fuel to be=20 ignited will be wood dust, and oxygen will usually be made available by=20 the use of some kind of notch. Now we can elaborate on specific=20 principles for each of the three elements, starting with heat.

=20

PRINCIPLE #1- WHEN WOOD IS RUBBED AGAINST WOOD, FRICTION OCCURS, AND=20 THIS FRICTION IS WHAT GENERATES HEAT. The idea in fire-by-friction is=20 thus to increase the heat-generating friction to a point where the heat=20 created is sufficient to ignite the fuel (which in this case is=20 combustible material in the form of wood dust). To increase friction,=20 there are three factors involved, which leads us to principle #2.

PRINCIPLE #2- FRICTION HEAT IS DETERMINED BY THREE FACTORS: SPEED,=20 PRESSURE AND COARSENESS OF MATERIALS. These three factors have=20 implications when trying to improve fire-by-friction practice. For=20 example, speed can be increased by making the spindle center smaller in=20 diameter and the burning end larger in diameter (gearing); pressure=20 needs to be increased to the maximum possible just prior to the=20 formation of the coal; and coarser-grained soft woods will create more=20 friction (under same pressure and speed) than finer-grained hardwoods,=20 which is one of the reasons why cedar, basswood and willow are all-time=20 favorites. =20

Of course, in practice, it is not so easy to increase friction. In=20

bow-drill, for instance, making the spindle thinner makes it easier for the rope to slip and also for primitive strings to break; adding pressure causes speed to decrease because of limits in one's physical strength; and wood choice is not always easy in a natural setting. However, the idea is to maximize the heat generated according to the specific fire-making situation.

Assuming that everything possible has been done to ensure maximum speed and pressure, (good bearing for the bow-drill spindle, proper bio-mechanics, good technique etc.) and assuming choice of materials is coarser than finer, we can now look at the quality of the fuel.

PRINCIPLE #3- THE TINDER TO BE IGNITED IS THE WOOD DUST FORMED BY FRICTION OF TWO SURFACES. When friction occurs, the result is wood dust. If there is no wood dust, it is because there is no friction. An example of this occurs when one tries to start a friction fire with very resinous wood, such as burned pine roots (pitch pine), and a slippery glaze forms preventing the formation of wood dust.

PRINCIPLE #4- VARIOUS WOODS AND WOODY PLANTS HAVE DIFFERENT POINTS AND SO WILL THEIR WOOD DUSTS. Various woods and plants will ignite at different heat levels, which means that the amount of heat required to form a coal is different for each. Generally, soft woods need less heat to ignite than hard woods, but individual species have to be studied to be more precise. The reason this is true is that the greater porosity of the soft woods permits the wood to dry more quickly when subject to heat, thus causing quicker ignition.

PRINCIPLE #5- THE WOOD DUST WILL BE FORMED MOSTLY OF THE SOFTER OF THE TWO SURFACES BEING RUBBED, BUT WOOD GRAIN DIRECTION MUST BE CONSIDERED. This is very important, because it directly affects the amount of heat required to ignite the wood dust. When the wood for fireboard and spindle are of the same wood, the spindle is harder than the fireboard in the sense that the fibers are cross-grain rather than with the grain. =

This means that more wood dust will come from the board than from the spindle. For the same reason, in the fire saw technique, more wood dust will come from the saw than from the board.

Suppose we are using a maple spindle on a cedar board. Since the maple is harder, and in addition, because the spindle fibers are cross-grain, most of the wood dust will come from the cedar board, and so the wood dust fuel will have the igniting properties of cedar. Now, suppose the reverse, that you are using a cedar spindle on a maple board. The maple board is harder, but the fact that the cedar spindle is rubbing cross-grain will offset that hardness somewhat, and the wood dust fuel will in large part be composed of maple, with much higher temperature needed for ignition.

PRINCIPLE #6- WHEN THERE IS ENOUGH FRICTION HEAT, MOISTURE IS DRIVEN OFF FROM THE WOOD DUST AS IT FORMS, CREATING SMOKE. At this point, the wood dust is drying, creating smoke, and it's temperature is rising close to the ignition point. When at this point, if fire-by-friction is unsuccessful, you will notice that the wood dust has started to char and turn blackish.

PRINCIPLE #7- TO OBTAIN A COAL, WOOD MUST BE RUBBED OVER AND OVER ON THE=20  
SAME WOOD DUST. The following is very important to understanding=20  
fire-by-friction theory. Usually, wood dust is light, and when you rub=20  
wood, the dust moves away from the friction area and thus cools off, and=20  
new wood is rubbed which creates new dust which is cooler. This means=20  
that theoretically, you can do this forever and never obtain a coal or a=20  
fire. Here is the main reason why you cut a notch in the fireboard: the=20  
hot dust gets wedged in the notch, preventing it from moving away from=20  
the friction area, and you are then rubbing over and over on the same=20  
wood dust and a coal will get created at that exact spot. The coal then=20  
spreads to the remaining wood dust, making it grow, creating sufficient=20  
heat to ignite other tinder.

Usually it is not sufficient to have the burnt wood dust wedged in a=20  
crack. There is also a weight consideration. The pile of wood dust=20  
must be big enough and therefore heavy enough to prevent the newly=20  
formed dust from moving it and cooling it off.

PRINCIPLE #7- THE COAL IS INITIALLY THE SIZE OF A SINGLE WOOD DUST=20  
PARTICLE, AND TO GROW, THERE MUST BE COMBUSTIBLE MATERIAL AROUND IT. =20  
Heat rises, and there must be sufficient wood dust particles above and=20  
around the coal so that they will also ignite from the initial heat. If=20  
there is not enough wood dust around the forming coal, it will not=20  
gather the momentum necessary to grow to usable size. Just like a fire=20  
can't be built with a match and a single stick, a coal cannot form if=20  
there isn't enough burnt wood dust immediately around it.

Now that we have looked at the heat and fuel parts of the=20  
fire-by-friction theory, lets examine the oxygen aspect.

PRINCIPLE #8- A FIRE NEEDS OXYGEN, BUT NOT AT THE EXPENSE OF REMOVING=20  
FUEL. This is the most important and at the same time the most=20  
difficult to understand aspect of fire-making. When building fires, you=20  
must force air between tightly packed fuel, not remove fuel to let air=20  
at it. That's why you blow and fan a fire. If you remove fuel to let=20  
air in, then there is nothing left to burn, and the fire goes out!

Now in fire by friction, a microscope reveals that a mound of wood dust=20  
particles resembles a pile of minuscule wooden boulders, with plenty of=20  
air space in between them. In fact, when a coal goes out, it is=20  
practically never because of lack of air, but almost always because of=20  
lack of fuel. In practice, this means that there is not enough quantity=20  
of accumulated wood dust, or that the wood dust was not left to stand=20  
still (shaking fireboard, rough drill movement), leaving too much air=20  
between particles. This is equivalent to a regular fire with sticks=20  
spaced too far apart. The flame from one stick does not reach the other=20  
stick, and the fire goes out. This means that theoretically, the notch=20  
is not necessary for air intake!

PRINCIPLE #9- AIR SPACES BETWEEN WOOD DUST PARTICLES DEPEND ON THE TYPE=20  
OF WOOD USED. When analyzing various wood dusts, several authors have=20  
noted the quality of wood dust as being fundamental to the success of=20  
fire-by-friction. Some woods yield round and "sticky" dust particles=20  
which bind together and are good for forming coals. Other woods yield=20  
long, thin and fibrous particles which are very poor for forming coals. =20  
The problem with this type of wood dust is not the inflammability=20

characteristics of the dust. It is simply that there is too much air between particles, so that sufficient heat transfer does not occur from one particle to the next for further ignition to take place. Again, this is like a regular fire with sticks spaced too far apart. One solution to this problem is to force the wood dust into an enclosed area which will compress it, using a wider-at-the-bottom notch, for instance. =

Another solution is to add a little fine sand to the hole in the fireboard, which tends to break the long pieces into smaller ones which will pack the notch more tightly. However, too much sand takes the place of fuel in the notch, with negative results.

Now that we have looked at the principles which affect the heat and oxygen necessary for forming a coal, we can answer a few frequently asked questions related to the above theory. =

-----  
CAN A BOW DRILL FIRE BE MADE WITHOUT A NOTCH? =

Yes, it is certainly possible. Just keep drilling long enough and hard enough so that the burnt wood dust pile around the friction area gets big and heavy enough not to move as you keep drilling. Then you will be rubbing over and over on the same wood dust and a coal will form. I have obtained up to 5 coals at once all around the drilling area this way.

CAN I SAVE TIME BY FILLING THE NOTCH WITH TINDER BEFORE I START? =

No, this will not work. Filling the notch with tinder will prevent a coal from forming, because there will be no space for the wood dust to accumulate. Even if some wood dust does accumulate and form a coal, the added tinder will not be fine enough to ignite from the little bit of heat produced by the miniature coal. =

ARE THERE WOODS WHICH WILL NOT WORK FOR FIRE-BY-FRICTION? =

Theoretically, no, all sound dry woods will work if sufficient speed and pressure are used, and if the notch is cut in such a way as to condense the wood dust into a tight enough pile. In practice, with the mechanical advantage of a perfect bow drill setup, in ideal conditions, I have yet to find a wood that will not generate a coal.

WHAT'S THE THEORY BEHIND THE FIRE SAW? =

Well, as the saw traverses the bamboo half round board, burnt wood dust accumulates underneath and you are rubbing back and forth on the same pile of wood dust which can't move because it's stuck underneath the board! =

As for the new "10 second upside down fire saw" technique, this was derived from the fire thong technique where the knife-edge of the hardwood replaces the thong. =

ACCORDING TO THEORY, HOW DOES THE FIRE THONG WORK? =

Fire thong works on exactly the same principle. The thong goes underneath a piece of wood which is split open about 1/4 inch, and burnt

wood dust accumulates above the thong and gets wedged in that split and can't move. Once the crack is full, the thong rubs back and forth against the same wood powder and the coal ignites there.

WHAT ABOUT THE FIREPLOW?

The fireplow technique is harder to understand and doesn't work everytime because it relies on brute strength to generate sufficient heat in the pile of wood dust to ignite a coal at a random spot in the pile. Since this technique cannot be duplicated precisely the same way everytime, it is hard to come to a conclusion about what is happening but I think it is this. As the pile of wooddust at the bottom of the plow gets heavy enough and cannot move, the heat transfer from the friction area ignites a coal on the bottom edge of the pile, which usually manifests itself as a coal on top of the pile when it is accidentally hit by the grinding stick. Note that I have tried making artificial fireplows by tying sticks to my jigsaw blade and was not able to produce fire! The principles are not respected accurately in this technique, and probably a random crack between the dust pile and the plow board must permit the formation of the coal.

IF THE COAL IS FORMED BY RUBBING OVER AND OVER ON THE SAME WOOD DUST, WHY DOES THE COAL USUALLY APPEAR SOME DISTANCE AWAY FROM THE BOARD AND NOTCH?

The explanation is that even when the wood dust pile is not quite heavy enough to hold in place, but partly so, sufficient friction occurs to form the small coal anyway before the new dust forces the pile (including the coal) over. You don't notice this because of all the smoke from the grinding of the wood. If the coal appears far away from the center, you are probably drilling too much for nothing- your coal was already formed several seconds ago. When you go for speed records on bow drill you learn precisely when the coal has formed, and that is always where the wood rubs against wood dust. Theoretically, you would think that the coal should form at the edge of the drill where the speed is fastest. But in reality it forms a little lower, where the wood dust is heavy enough not to move. That's why you don't see it right away why it seems to catch further away in the wood dust pile. Another demonstration that the coal forms next to the spot being rubbed is when you don't quite achieve a coal. You will notice the black char which almost made a coal right near the edge.

HOW FAST CAN A COAL BE MADE?

I'm not really sure what the ultimate limit could be. According to theory, there has to be enough time to fill the notch so that the dust will no longer move before a coal will form. Under laboratory conditions, using an ideal bow drill set and starting with an empty notch, I have made coals in under 4 seconds.

SHOULD I FAN A COAL RIGHT AWAY AS SOON AS I STOP THE FRICTION?

Usually yes, but this depends on the dust pile. Theoretically, just like in regular fire starting, you blow when the fuel is piled tightly. If the dust pile is tight and the notch is wider at the bottom, I usually fan the coal very quickly with my hand. I do not blow on it at first because of the moisture on my breath. Sometimes, when the wood

dust is somewhat loose, I do not fan it at all.

-----

CONCLUSION:

This article is an effort to outline various theories and principles of fire-by-friction based on informal observations made during considerable experimentation of the various techniques in the past 23 years. The information is offered solely as a starting point for further scientific investigation, which might reveal errors in the above theories and principles. The reader should keep this in mind.

andre good post,

in your post you have placed emphasis on heat generation.

another angle of approach is to also think about heat retention and concentration. this brings into play the thermal conductivity, and specific heat of the material, as well as the geometry of

the "oven" or heat store volume.

from this approach it's easy to see the action of moisture and water vapor as the big heat thief, and some of the other factors involved in fire by friction.

you can generate a lot of heat, but if you cant concentrate and store it, your just burning calories.

For fire piston, "mountain' Mel Deweese is the only expert I know and he says he has only had success with tinder derived from a certain palm. I know that's a vague reference, I'll try to find out the xact name of the palm. In the meantime anyone who wishes to contact Mel, can contact him at: Nature Knowledge, 1825 Linden St., Grand Junction, CO 81503, Phone: 970-242-8507.

As far as flint & steel, I have only had success with charred material and an uncharred fungus from up in Canada that a friend of mine brought me at TRIBE Gathering. Amazing stuff. A small sliver catches a spark and it glows and glows. Maybe Andre remembers the name of the fungus I'm talking about. George Hedgepeth brought it with him that year you came to TRIBE Gathering.

I received a very important post in french from Pascal Chauvaux of  
France who is a member of our group. For those who don't read french, I  
have translated the essential at the end of this:

>AndrÈ,

Merci de m'avoir indiquÈ le PRIMITIVE-SKILLS-GROUP !

J'ai rencontrÈ quelques difficultÈs pour m'abonner, mais tout est bien  
maintenant.

J'ai re u d' jy plus de 80 messages, et cela semble bien int ressant. Un des domaines qui m'attire le plus est la production de feu. Nous avons, avec quelques amis d'une association arch ologique de la r gion de Li ge en Belgique, beaucoup travaill  la production (pr historique) du feu. Si cela t'int resse, je peux t'envoyer la copie d'un article que nous avons publi  (en Fran ais) :  
L'obtention du feu par percussion : approche exp rimentale et trac ologique, in Bulletin des Chercheurs de la Wallonie, Tome XXXI, 1991, 19-49.  
On y parle notamment des initiateurs (champignons) test s.

J'ai de bons contacts avec des arch ologues suisses, et j'ai re u un article indiquant les champignons utilis s (une quinzaine) par les n olithiques du lac de Neufch tel en Suisse. Quelques-uns  taient des initiateurs pour le feu.

En ce qui concerne le feu par friction et percussion, je connais un bon sp cialiste fran ais : Jacques Collina-Girard. Il a publi  quelques articles int ressants, et je peux t'en faire parvenir une copie si cela t'int resse.

Nous nous sommes sp cialis s dans les briquets en fer, et j'en ai d'ailleurs forg  une quarantaine la semaine derni re. Il faut dire que nous avons fait des recherches r cemment, et que la plus vieille occurrence d'un briquet en fer remonte   400 BC. Il s'agit de 3 briquets en fer provenant d'une s pulture collective de l' ge du fer (La t ne), dans la grotte Ambre,   Eprave en Belgique. Ils ont une forme tr s diff rente des briquets en fer connus. J'en ai quelques copies, et si tu es int ress , je peux t'en faire parvenir un (avec les dessins des pi ces originales). Je voudrais d'ailleurs le faire savoir au PRIMITIVE-SKILLS-GROUP. Peux-tu leur transmettre un message leur proposant gracieusement un briquet en fer. Je m'engage   envoyer gratuitement un briquet et quelques explications   ceux qui m'en feront la demande.

Comme chaque ann e, le premier jour de l'an, je vais me promener au Cap Blanc Nez, au bord de la mer entre la France et l'Angleterre, o  ils ont creus  le tunnel sous la manche. On y trouve du silex dans la craie, mais aussi  norm ment de marcassite, le fameux bisulfure de fer qui est attest  comme le plus ancien proc d  de production de feu (tant que l'on ne retrouve pas une drille en bois). J'ai toutes les r f rences des sites o  on a retrouv  de la marcassite (pal o sup rieur). Je peux  galement t'envoyer un kit complet : marcassite, briquet en silex, amadou.

Voilà, j'espère que si des renseignements que je te fournirai sont intéressants, tu auras le courage d'en faire une traduction sommaire pour le faire savoir aux membres du PRIMITIVE-SKILLS-GROUP. Mon anglais n'est pas assez bon pour le faire moi-même.

Merci pour ton obligeance.

Meilleurs voeux de santé et de prospérité à l'occasion de l'année nouvelle, à toi et aux membres de ta famille.

Pascal Chauvaux  
Pascal.Chauvaux@gate71.be

Ok, here's the gist of the post:

Pascal and others in France in archeological circles have worked severely hard for a long time on flint & steel tinder. They found references to 15 types of fungi which were used for flint & steel tinder and tested them. He has offered to send me scientific articles on all of these experiments conducted in Europe and Switzerland especially, but they are in french.

His group has specialized in making striking bats based on a very old one they discovered which is dated 400 BC. These bats are apparently quite different from the ones we know about.

Pascal has offered to send a replica and drawings of the original to those of the group who want one free of charge! (I'm not sure that he will be able to do this when he finds out how many of us will be interested!)

He says that in the undersea tunnel which was dug years ago between England and France, that they have discovered Marcassite and other evidence of primitive fire making ways.

Wow, thanks for such a great post, Pascal, and in the name of the group, thanks for such a generous offer.

Please, everyone, send your requests directly to Pascal by private E-mail, not to the group.

André

I have found that the dried top of the cattail that has been broken up and fluffed up will catch a spark from flint and steel very easily. In fact, if you do not watch out, the explosion of the initial flame will burn your hands before you can get out of the way.

Jim W.

Ok Jim, you had me fooled there for a while! What you are referring to is a commercial flint striker which is made of magnesium with a striking insert made of (what's the name I'm searching for?) ium. This magnesium match puts off a very very hot spark that will make just about any kind of good tinder flame up.

However, when we talk about flint and steel here, we are talking of natural flint pieces struck with a piece of steel. I don't know of anyone who has found any natural tinder fine enough to catch that kind of spark other than the fungus Inonotus obliquus. That's why I was so

surprised by the cattail story.

Just goes to show how simple details can mislead one's thinking and get some authors writing down things which do not work.

Thanks for helping us clear this up.

I was using a simple flint striker that fit into the side of a knife handle that I had ordered from the Sportsmans Guide Magazine. I just raked the knife blade along the length of the flint piece (about 2.5in. long X 1/8in wide), and got a large swoosh of sparks that when done close to the little pile of cattail fluff, resulted in an explosion of flame. The fluff burns out rather quickly, but with some dry leaves or other tinder next to it, results in a nice warm camp fire.

I received a very important post in french from Pascal Chauvaux of France who is a member of our group. For those who don't read french, I have translated the essential at the end of this:

>Andr ,

Merci de m'avoir indiqu  le PRIMITIVE-SKILLS-GROUP !

J'ai rencontr  quelques difficult s pour m'abonner, mais tout est bien maintenant.

J'ai re u d' j  plus de 80 messages, et cela semble bien int ressant.

Un des domaines qui m'attire le plus est la production de feu. Nous avons, avec quelques amis d'une

association arch ologique de la r gion de Li ge en Belgique, beaucoup travaill  la production

(pr historique) du feu. Si cela t'int resse, je peux t'envoyer la copie d'un article que nous avons

publi  (en Fran ais) :

L'obtention du feu par percussion : approche exp rimentale et trac ologique, in Bulletin des

Chercheurs de la Wallonie, Tome XXXI, 1991, 19-49.

On y parle notamment des initiateurs (champignons) test s.

J'ai de bons contacts avec des arch ologues suisses, et j'ai re u un article indiquant les

champignons utilis s (une quinzaine) par les n olithiques du lac de Neufch tel en Suisse.

Quelques-uns  taient des initiateurs pour le feu.

En ce qui concerne le feu par friction et percussion, je connais un bon sp cialiste fran ais : Jacques

Collina-Girard. Il a publi  quelques articles int ressants, et je peux t'en faire parvenir une copie

si cela t'int resse.

Nous nous sommes sp cialis s dans les briquets en fer, et j'en ai d'ailleurs forg  une quarantaine la

semaine derni re. Il faut dire que nous avons fait des recherches r cemment, et que la plus vieille

occurrence d'un briquet en fer remonte   400 BC. Il s'agit de 3 briquets en fer provenant d'une

s pulture collective de l' ge du fer (La t ne), dans la grotte Ambre,   Eprave en Belgique. Ils ont

une forme tr s diff rente des briquets en fer connus. J'en ai quelques copies, et si tu es int ress ,

je peux t'en faire parvenir un (avec les dessins des pi ces originales). Je voudrais d'ailleurs le

faire savoir au PRIMITIVE-SKILLS-GROUP. Peux-tu leur transmettre un message leur proposant

gracieusement un briquet en fer. Je m'engage   envoyer gratuitement un briquet et quelques

explications   ceux qui m'en feront la demande.

Comme chaque ann e, le premier jour de l'an, je vais me promener au Cap Blanc Nez, au bord de la

mer entre la France et l'Angleterre, o  ils ont creus  le tunnel sous la manche. On y trouve du silex

dans la craie, mais aussi  norm ment de marcassite, le fameux bisulfure

de fer qui est attesté  
comme le plus ancien procédé de production de feu (tant que l'on ne  
retrouve pas une drille en  
bois). J'ai toutes les références des sites où on a retrouvé de la  
marcassite (paléo supérieur). Je  
peux également t'envoyer un kit complet : marcassite, briquet en silex,  
amadou.

Voilà, j'espère que si des renseignements que je te fournirai sont  
intéressants, tu auras le courage  
d'en faire une traduction sommaire pour le faire savoir aux membres du  
PRIMITIVE-SKILLS-GROUP. Mon anglais n'est pas assez bon pour le faire  
moi-même.

Merci pour ton obligeance.  
Meilleurs voeux de santé et de prospérité à l'occasion de l'année  
nouvelle, à toi et aux membres de  
ta famille.

Pascal Chauvaux  
Pascal.Chauvaux@gate71.be

Ok, here's the gist of the post:

Pascal and others in France in archeological circles have worked  
severely hard for a long time on flint & steel tinder. They found  
references to 15 types of fungi which were used for flint & steel tinder  
and tested them. He has offered to send me scientific articles on all of  
these experiments conducted in Europe and Switzerland especially, but  
they are in french.

His group has specialized in making striking bats based on a very old  
one they discovered which is dated 400 BC. These bats are apparently  
quite different from the ones we know about.

Pascal has offered to send a replica and drawings of the original to  
those of the group who want one free of charge! (I'm not sure that he  
will be able to do this when he finds out how many of us will be  
interested!)

He says that in the undersea tunnel which was dug years ago between  
England and France, that they have discovered Marcassite and other  
evidence of primitive fire making ways.

Wow, thanks for such a great post, Pascal, and in the name of the group,  
thanks for such a generous offer.

Please, everyone, send your requests directly to Pascal by private  
E-mail, not to the group.

André

I have found that the dried top of the cattail that has been broken up and fluffed up will catch a spark from flint and steel very easily. In fact, if you do not watch out, the explosion of the initial flame will burn your hands before you can get out of the way.

Subject: Tinder for fire piston and flint & steel

Content-Transfer-Encoding: 8bit

X-MIME-Autoconverted: from quoted-printable to 8bit by chic1.saglac.qc.ca id AAA19601

Content-Type: text/plain; charset=iso-8859-1

X-Mozilla-Status: 0001

I have been communicating with Wyatt Earl who wrote the article on fire piston and was asking him about tinder other than charred cloth. Our communications might interest some of you... here goes.

Howdy Andr !

First, thank you so much for your generous and kind appraisal of my fire piston article. It was a lot of work but very fun.

I am glad that you brought up the question of the shredded bark tinder that was mentioned in the article. I was reporting what John Rowlands said he used but in all my years of experimentation on the subject of catching sparks I have never had any succes with the dry, finely shredded bark. In addition, no one who is into primitive tech. that I have talked to has indicated success either. Ditto for mouse or birdnests. I have only had success with charred material. The only thing I have seen that is uncharred that will catch and nurture a spark is a type of fungus that is sometimes found in birches or cherry trees and it is amazing to see.

Because of your question I am going to edit my article to indicate the above observations. I appreciate you input and look forward to further conversations as well. It sure would be fun to make a living writing things like that firepiston article.

Happy Holidays, Andre

Hi Wyatt,

You might like to know that I have finally identified that birch fungus you are talking about. It is sometimes called Chatoquin or Bearshit but the scientific name is *Innonotus obliquus*. It is indeed a fungus (at first I thought it was a disease) but it is a white rot fungus rather than a brown rot like most rots we usually see. This white rot attacks the wood lignum and cellulose differently than brown rot and is responsible for forming a material which is similar in many ways to charred cloth. I am still looking into this and trying to find other fungi or material botanically related to *Innonotus* to try them out. Maybe this will help you with the tinder issue and maybe you and others can help pursue this research further.

*Innonotus* was also used medicinally in Russia, one source mentioned that (can't remember off hand, but I did write it down somewhere).

For tinder, this stuff is indeed amazing. One very fine spark into it and you can't put it out! However, I've noticed that if it dries out too dry, it no longer works. Much testing still to be done...

Best regards,

Andr 

PS We've got a great primitive skills group with many very knowledgeable leaders, you are very invited to join us!

X-Mozilla-Status: 0001

Andr ,

Merci de m'avoir indiqu  le PRIMITIVE-SKILLS-GROUP !

J'ai rencontr  quelques difficult s pour m'abonner, mais tout est bien maintenant.

J'ai re u d' j  plus de 80 messages, et cela semble bien int ressant.

Un des domaines qui m'attire le plus est la production de feu. Nous avons, avec quelques amis d'une

association arch ologique de la r gion de Li ge en Belgique, beaucoup travaill  la production

(pr historique) du feu. Si cela t'int resse, je peux t'envoyer la copie d'un article que nous avons

publi  (en Fran ais) :

L'obtention du feu par percussion : approche exp rimentale et trac ologique, in Bulletin des Chercheurs de la Wallonie, Tome XXXI, 1991, 19-49. On y parle notamment des initiateurs (champignons) test s.

J'ai de bons contacts avec des arch ologues suisses, et j'ai re u un article indiquant les champignons utilis s (une quinzaine) par les n olithiques du lac de Neufch tel en Suisse. Quelques-uns  taient des initiateurs pour le feu.

En ce qui concerne le feu par friction et percussion, je connais un bon sp cialiste fran ais : Jacques Collina-Girard. Il a publi  quelques articles int ressants, et je peux t'en faire parvenir une copie si cela t'int resse.

Nous nous sommes sp cialis s dans les briquets en fer, et j'en ai d'ailleurs forg  une quarantaine la semaine derni re. Il faut dire que nous avons fait des recherches r cemment, et que la plus vieille occurrence d'un briquet en fer remonte   400 BC. Il s'agit de 3 briquets en fer provenant d'une s pulture collective de l' ge du fer (La t ne), dans la grotte Ambre,   Eprave en Belgique. Ils ont une forme tr s diff rente des briquets en fer connus. J'en ai quelques copies, et si tu es int ress , je peux t'en faire parvenir un (avec les dessins des pi ces originales). Je voudrais d'ailleurs le faire savoir au PRIMITIVE-SKILLS-GROUP. Peux-tu leur transmettre un message leur proposant gracieusement un briquet en fer. Je m'engage   envoyer gratuitement un briquet et quelques explications   ceux qui m'en feront la demande.

Comme chaque ann e, le premier jour de l'an, je vais me promener au Cap Blanc Nez, au bord de la mer entre la France et l'Angleterre, o  ils ont creus  le tunnel sous la manche. On y trouve du silex dans la craie, mais aussi  norm ment de marcassite, le fameux bisulfure de fer qui est attest  comme le plus ancien proc d  de production de feu (tant que l'on ne retrouve pas une drille en bois). J'ai toutes les r f rences des sites o  on a retrouv  de la marcassite (pal o sup rieur). Je peux  galement t'envoyer un kit complet : marcassite, briquet en silex, amadou.

Voila, j'esp re que si des renseignements que je te fournirai sont int ressants, tu auras le courage d'en faire une traduction sommaire pour le faire savoir aux membres du PRIMITIVE-SKILLS-GROUP. Mon anglais n'est pas assez bon pour le faire moi-m me.

Merci pour ton obligeance.

Meilleurs voeux de sant  et de prosp rit    l'occasion de l'ann e nouvelle,   toi et aux membres de

ta famille.

OK, I'm like brand new here. As if the question I'm about to ask won't tip you off.

Where is the best place to find flint? And is there anyplace that commercially sells it?(In chunks that is, not in a fire starter kit or anything like that).

If you are using it for flint & steel fire making you don't necessarily have to use genuine flint. Any stone that is volcanically produced and high in silica will work. Here are a list of suppliers, I know about, though, for flint and other knappable material. I also have some pieces if you just want to make flint & steel fire with them for \$3 a piece (ppd):

Billy Joe Sheldon, 133 E. 4th Ave., Springfield, CO 81073, Phone: (719) 523-4434

Sells alIbates flint.

Dan Stueber, 5009 N. Girard, Portland, OR 97203

Sells scribes (For signing work).

Flintworks, Scott K. Silsby, 6604 Placid St., Falls Church, VA 22043, Phone: (703) 533-0056

Scott is the best teacher and tool maker when it comes to greenstone tools. He also teaches workshops in flintknapping, bow and arrow making and sells greenstone and greenstone tools. Greenstone sells for \$2.00

lb. (\$30.00 min. order), axe and adze blanks for \$10.00 each (prices do not include UPS).

Jim Regan, 23 107 Erskin St., NE, Bethel, MN 55005, Phone: (612) 462-5568

Sells Brazillian agate slabs, percussion and flaking tools.

Native Way, P.O. Box 159, Washington, Mississippi 39190

Sells stone, tools and more.

Nemec Stone Co., Box 178A, Jarrell, TX 76536, Phone: (512) 746-5221 (evenings)

Sells several varieties of Texas flints.

Neolithics, Carl Ratzat, 1530 B St., Springfield, OR 97477

Sells obsidian and dacite.

Richardson's Rec. Ranch, Ltd., Gateway Rt. Box 440, Madras, OR 97741

Sells stone.

T&J Copper Supplies, 1411 Blue Smoke, San Antonio, TX 78231

Copper supplies

Vision Maker Co., 116 Mt. Carmel Dr., Natchez Mississippi 39120

Sells tools, stone, reproductions.

Stephen,

I teach about fifty kids each year to start flint & steel fires. My favorite steel striker is the edge of a common file. I collect a couple dozen ski files from the local ski shops every winter and break them into 3-4 inch pieces with a hammer so I can give each child their own set. All files work, but the best ones have smooth edges. You can grind the edge ribs off with a grinder if you want.

Once you have a steel striker it is easy to find workable "flint" rocks. Just pick up rocks everywhere you go and strike the steel against a sharp edge and watch for sparks. You will be surprised at what all will work. Any rocks with a high silica content will work, \*except glass\* (natural and artificial) which is too brittle. The edge of the rock has to be sharp to shear off little bits of metal from the file. The sparks are globs of burning metal.

Always Peace,

Thomas J. Elpel

>

Someone correct me if I'm wrong on this, but my understanding of the theory behind flint and steel sparks is that the flint cuts off a piece of metal quickly which generates heat and sends a piece of hot metal flying which is the spark. Different flints are harder and sharper and will send a larger piece of metal flying, ie bigger spark.

If all this theory is true (my unverified assumption), then the reason iron pyrite will be so hard to use is that the metal pieces in the pyrite are too small, and the strike with flint or quartz cannot pull off a large enough piece of metal to cause a good spark.

Anyone know more about this or care to comment about this theory?

Thanks for sharing,

AndrÈ

I'm not too sure about the size of the sparks being the key factor here,

although you are right about it being the flint's job to shear off pieces of steel. I'm not sure of all the science on this, but I do look for orange sparks when testing a fire steel. Yellow sparks indicate too soft of a steel and usually are not hot enough to do the job. On the other hand, you may have worked with some 'cooler' sparks for firemaking in other techniques. So, correct me if I'm wrong.

HI Ben,

I'm convinced that size of sparks is an important factor! For example, although ferritorium (sp.) is probably the best steel from which you can scrape a spark, the small sparks caused by rubbing the ferritorium of a Bic lighter are not sufficient to start a fire.

Are not the orange vs yellow sparks caused by the quality of the flint rather than the quality of the steel? Or partly so?

I may be dead wrong on this one, and I'd sure like a metallurgist or someone else to clear this up. I'll do more research, meanwhile if anyone has any ideas...

>snipped for brevity, but I agree.

Your theory is supported by actual use. Early firearms developed with the wheellock. I have not read any evaluation of this but, the constantly rotating wheel ensures that a sufficient quantity of hot sparks are produced using the cutting material at that time... not flint but iron pyrite. The effect of the wheel is to provide a loooong striking surface for the pyrite and plenty of sparks to ignite the priming charge.

Well, I said in reply to Benjamin that I thought that the smaller crystals in a large mass were better than the larger crystals in fewer numbers. I think this may be because you get more individual sparks, even though they're smaller. I don't remember questioning spark size.

This should hold your theory true, Andre, smaller sparks, but more of them

Hmm another one for experiment. How can I keep strike pressure the same so as to make meaningful the outcome of using several different materials together.

Take Care  
Merv

I may be off the mark here, but I have yet to find any reference for the use of flint and steel in the Americas before the coming of the Europeans. I believe that hand and bow drills figured in the lion's share of fire making implements, with fire bundles and fire conservation also being important. The only other report of firemaking that didn't use a bow drill was a vague reference to the use of what might have been a crystal lense in a ritual from the Andes in which the sun started the first fire of the year or some other such ritual.

You are probably right, when you say the 'lion's share' but there *\*are\** a few examples of percussion fire starting. Diamond Jenness, in Material Culture of the Copper Eskimo (1946:5,55) reports observing Iron pyrites used for fire starting. I don't have the original handy, but the source citing Jenness says that the pyrites were struck together. The same technique -- pyrite on pyrite was also used by the Beothuk in Newfoundland and Ingeborg Marshall, in A History and Ethnography of the Beothuk (1996:302) says:

"The Beothuk lit fires by striking two pieces of iron pyrite together to produce sparks that would ignite bird down or other inflammable matter. Five Beothuk burials contained iron pyrites among the grave goods; fragments of pyrites were also recovered from several housepits on archaeological sites. The use of metallic crystals for percussion striking was the main method of producing fire among Algonkquian speakers north of the Gulf of St. Lawrence. Le Jeune, who described this procedure from the Montagnais in Labrador in 1634, said that they used the down-covered skin of an eagle's thigh to catch the sparks."

We found Iron Pyrite nodules in prehistoric Dorset sites in the central High Arctic and they have been identified as far starters. We experimented with them a bit in the lab and couldn't get very good results banging them together. They had been lying more or less exposed on the surface for 800-1000 years, (not much soil formation in the high arctic) so perhaps the 'rind' suggested in another post was too thick? Our experiments may also have been somewhat half-hearted as they *\*were\** artifacts. We did try them against a Hudson Bay steel and got showers of sparks. There were lots of meteoric iron tools found in the same site (as well as quartz crystals) so maybe the pyrite was stuck against this iron? It makes sense, though, that in the far north where the only wood is driftwood to use a fire starting technology that isn't dependant on plant fibers.

cheers,  
Tim

I'm convinced it is the quality of steel. Hard, hi-carbon steel throws good 'hot' orange sparks. I can use the same good firesteel on many different 'flints' (I use that term loosely) and get tyhe same orange sparks. I have used quartz, rhyollite, various cherts and lots of other stones. In fact I take a piece of rhyollite with me to the flea market

and test old worn out files for their hardness. If they throw good orange sparks, I buy them, bring them home, break them in shorter pieces, grind one edge smooth and have plenty of fire steels to pass around.

The most common is the steel from a file.

I must wear sunglasses when I strike a light with my file steel striker...

If you are interested in, will send to you a typical European Iron Age striker (a free gift).

Subject: Native Americans flint and steel firemaking tools

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

Hello,

Who knows what kind (shape) of steel striker Native Americans used? In page 144 and 145 of a book of Jim Hamm (Bows and Arrows of the Native Americans), I can see quivers with bags for flint and steel firemaking tools, but not the shape of the tools. Thank you for sharing your knowledge.

Hi Pascal,

All of the ones I've seen sold in museums and forts in Canada, (I've toured extensively) look like a fairly square C the size of 4 fingers with a 1/4 inch circle recurve at the top for a better grip for the thumb. They are about 1/4 inch wide and 1/8 inch thick.

Substitute Iron Pyrite and Iron Ore for the steel we use. The shape is whatever you find. The points on the Iron Pyrite are nice. Quartz works almost as well as flint. (In flintlocks too!) I don't know of any special shaping done to firemaking tools.

I don't remember wher I read or heard this.

A fire horn was used to transport a coal. That'd be a horn that was hollow,

like a cow or buffalo horn. Filled with punk and/or moss and/or cattail fluff, and/or anything else you can find that would burn slowly in a low oxygen atmosphere. The horn was sealed, but not tightly.

Now... can anyone verify this info?

Merv

Merv,

That special last week on Discovery spoke about the forest people of the Congo, apparently they have no traditional knowledge of how to start fire, they rely on carefully preserved coals carried in a similar manner to restart fire even while on long journeys. So each and every fire is a link to long dead ancestors that managed the continuence of the original spark. Some one asked if I felt that it was possible to be dropped naked into a survival situation and survive. I believe it is possible or I wouldn't be involved in the study of primitive skills. I've been interested in survival since I was very young. After making several survival kits of various sizes, I recognised the weakness of modern survivalism. It was too gadget oriented. What do you do if you don't have the Rambo wonder knife, or designer load carrying gear, with G.I. Joe popup tent. I realized that the only survival kit I really needed was my head and what ever knowledge I could retain. A flake tool can take the place of a knife (or an easily made wooden stiletto depending on the need), a debris lean to can take the place of the pop tent. The concept of becoming native to a place can be a goal as well. Learning what foods to gather, where to find water, how to stay cool or warm ( in the desert both are important)

Have you tried Iron Pyrite and quartz? If you have tell me more. I have not had any luck with it. My guess is that the Iron Pyrite is not hard enough to produce hot enough sparks.

In a message dated 97-01-07 01:55:41 EST, you write:

>Who knows what kind (shape) of steel striker Native Americans used?

Steel strikers were introduced to the Native Americans by European Colonists so they used those received in trade. Steel strikers were a common trade item and are mentioned in many early documents that list trading inventories of expeditions. Pre-contact Native Americans naturally had no steel implements, however it would be interesting to know at what point blacksmithing and metalworking was developed among the Native Americans and if, indeed they developed any improvements or adaptations. I do not know of any but it would be an interesting line of inquiry.

Where there any pre-contact methods used to light fires by sparking such as iron pyrite or other minerals? And what impact did the introduction of easier or different fire lighting methods have on pre-steel cultures?

Here are a couple of places that may be able to answer your questions with more authority than I

Whew, you're stirring up some good memories there. Cutting rocks with my  
 grandfather in his rock shop and just playing.

Yes I have tried quartz and iron pyrite. It gave good sparks on the bench.  
 (read as, not in a survival situation, but in a nice safe shop.) Iron  
 pyrite does seem to have a "rind" of weathered material on the outside. The  
 inner stuff works better, at least for me.

Now, the best result I had with pyrite was with a large mass of small  
 crystals, rather than one or two large crystals. It seemed to help if the  
 quartz face was fresh too. (I dropped my striker and it broke!) Oh, I did  
 strike the iron pyrite with the quartz, not the other way around. Don't  
 know why, just did.

I'll see it I can get the materials to try again.

take Care

Greetings from Eric`s Rocks and such!!!!!!!!!!

I thought i give you all a update on materials.

BRANDON FLINT ENGLAND \$2.65 LBS NODULES 10LBS TO 100LBS.

INDIANA HORNSTONE I JUST HAVE 40LBS LEFT TELL THE GROUND DRY UP . \$2.00  
A POUND PLUS SHIPPING & HANDLING.

AGATE FROM RHODE ISLAND \$4.00 A LBS PLUS SHIPPING AND HANDLING.

BEGINNING IN THE SUMMER OF 97 WE HOPE TO HAVE LARGE SUPPLY OF SLABS OF  
BRANDON FLINT AND HORNSTONE.

CARVING STONE

Arcadian Butterstone from south africa \$2.50 a pound plus shipping and  
handling.

Soapstone \$2.00 a pound plus shipping and handling.

Indiana slate sheet gray and red plus shipping and handling.

11 5/8 x 8 3/4 , 3/8 thick \$7.00 each.

11 5/8 x 5 5/8 , 3/8 thick \$6.00 each.

8 5/8 x 5 5/8 ,3/8 thick \$5.00 each.

7 1/4 x 4 5/8 ,1/4 thick \$4.00 each.

5 5/8 x 5 5/8 , 3/8 thick \$3.00

ARROWHEAD OCARINA MUSICAL FLUTE INSTRUMENT \$35.00

FIRST SOUTHEN INDIANA FLINT KNAP-N JUNE 20-22 1997

Hi John, to answer your question (which is quite valid), I refer you to the following exerpt from the primitive skills group welcome page:

"The main purpose of this group is to provide a way by which all lovers of primitive skills can discuss various subjects related to wilderness ways.

Topics which you are encouraged to discuss with other group members are:

1. All primitive wilderness living skills such as shelter, fire, cordage, primitive tanning, natural foods, primitive living, primitive rafts & boats, primitive direction finding, primitive trapping techniques, weapons for wilderness survival, primitive hygiene, protection from insects, primitive weather prediction, fighting cold, primitive medicine, traditional dog sledding, edible plants etc.
2. Subjects related to modern realistic wilderness survival, such as surviving unexpected emergencies after airplane crashes, broken down snowmobiles etc.
3. Discussions about environmental concerns related to the practice of primitive skills are also welcome.

Remember! This group is intended for fun, sharing and learning about primitive wilderness survival and living skills. All members will be asked to refrain from discussing topics related to specific religious, political or ethnic views."

In number 2 above, learning how to make a fire with a gun might save a hunter's life when he gets lost in the wilderness. That's why the subject is welcome on this list.

Hope this answers your question.

I have made fire with my flintlock musket by plugging the touchhole, blowing out the priming, and then placing a peice of charcloth into the pan. when you close the frizzen and the spark the peice the charcloth is lit by the resultant shower of sparks and can be blown into a flame. BTW i am going to try to make a fire piston out of a cut off peice of my musket barrel - would this be considered fire with guns? (ha-ha) -ketil

I've made fire with normal shotguns by placing tinder material in a heap enclosed by a fence of sticks driven into the ground or in a hole under a root (to prevent tinder pile from blowing away). Maybe this would work with airguns too?

Thanks to Andr  and all the other list member that have given feed back on this question of mine. I think, that if barrel lube can produce muzzle flash with an airgun (as seen after dark) than a little barrel lubing may be a way to get some contained tinder started. I reason that the gas compression from an airgun's cylinder may be greater than that produced from manual operation of a fire piston. I figure the muzzle

flash might be either attributed to electrostatic discharge, ignition of the device's petroleum based lubrication or simple ignition of airborne dust particles. As for a muzzle-end tinder containment add-on, I agree that a captive plug with a blind-end would be best for gas compression, but would likely blow off like a pop-the-cork toy gun. Radial (small side ports) venting (screened possibly) might be sufficient for enough compression to ignite tinder. However, putting an air gun up to a socket on a fire piston should also work.

Thanks, this has been fun.

Chris

I have made fire with a muzzle loading rifle by placing cloth or some other tinder in the barrel loosely and then firing it into the air. Sometimes it takes a couple of attempts, but it gradually comes down flaming. I have heard this could be done with a shotgun also if one carefully removes the shot in the shells down to the wadding and then firing it into the air.

The main problem with springpiston airguns is that while being simple in operation they can be easily damaged by dieseling. That causes damage to the springs and the piston seal. Also it would take a very special tender to be small enough to pass down an airgun barrel and still hold together long enough to be found and then used for firestarting. I've tried the felt cleaning pellets without success, and trust me DO NOT SHOOT TOWARD YOUR HAND AND TRUST THAT ANY PAD WILL STOP THE FORCE OF, OR PENETRATION OF THE FELT PELLET. Forgive me for shouting, but benefit by one of my moments of supidity. Air rifles can be good, quiet foraging tools for small game, but if you rely on it for small game hunting don't risk it for fire making. You will be encouraging conditions that shorten the life of your tool.

The main problem with springpiston airguns is that while being simple in operation they can be easily damaged by dieseling. That causes damage to the springs and the piston seal. Also it would take a very special tender to be small enough to pass down an airgun barrel and still hold together long enough to be found and then used for firestarting. I've tried the felt cleaning pellets without success, and trust me DO NOT SHOOT TOWARD YOUR HAND AND TRUST THAT ANY PAD WILL STOP THE FORCE OF, OR PENETRATION OF THE FELT PELLET. Forgive me for shouting, but benefit by one of my moments of supidity. Air rifles can be good, quiet foraging tools for small game, but if you rely on it for small game hunting don't risk it for fire making. You will be encouraging conditions that shorten the life of your tool.

I wonder if you would have more luck trying to light a fire with a rifle if you put a flash suppressor on it. These hexagonal devices, which you find on the end of every M16, channel the flame that comes out of the

rifle into six narrow channels out to the side.

You can also get flash suppressors with only 4 of the 6 channels open; I believe this is so you can counter the rifle's upward kick by pointing the closed channels down. It also provides a more intense flash out of the 4 remaining channels and should work better.

Problem is that threaded barrels are generally illegal in the US.

Phil

They are? Please explain. I can think of several examples which are widely marketed (AR-15, Swedish M-96 & M-38, Winchester and Browning rifles equiped with B.O.S.S. device). This doesn't mean you are wrong, you might be ahead of the feds on this. TIA.

This might be a regional thing. As far as I know there is no problem owning a weapon with screw threads cut onto the barrel end. What is regulated is the possession of a silencer. This isn't illegal to own but heavily taxed,

and severely regulated. As long as it isn't illegal to own locally, you can work through your local sherrif's office and Class 3 dealer to obtain a class 3 tax stamp to own either a fully automatic weapon or a silencer. I fired enough full auto while in the army, and the only ones I thought were any good were tripod mounted, you could really reach out and touch someone, otherwise they were a waste of ammo. Silenced weapons on the other hand, well lets say I like them, but for a \$300 tax stamp and all of the trouble you have while you own them(you must notify the BATF and all law wnfocement agencies ahead of time before you are going through their areas when you are moving the weapon. If you are relocated by your company you bettered hope that silenced weapons are not illegal in that area, or you will have to find someone to store your weapon with) they may not be worth the trouble. Besides that, they really don't cut down the sound much more than you would experience with a rifle barrel and CB caps. My apologies for straying into non-primitive weapons as far as I have.

JB

>ones and dry them?

I didn't know it was Ishi's favorite, but now I'm even more excited  
about buckeye. :-)

I have yet to collect any mullein, so I can't compare them. I've  
seen mullein down around Santa Barbara, but not up here in the SF  
Bay Area. I suspect it's out there; I just haven't noticed it.  
I've only been into primitive skills since last May. Buckeye is a  
tree, by the way, not a little plant like mullein. Did Ishi use  
very young saplings, or branches? I suppose it would have been easy  
to collect the seeds and grow saplings especially for this use??

I collected all the buckeye I've ever used from a single tree  
situated between a creek and a road. It suffered winter storm  
damage and I cut some logs from a large-diameter downed branch. I  
then cut the logs into spindles and fireboards, and have quite a

large stockpile. I've also used alder since it's a common wood, but alder's tougher to get a coal with. The buckeye that I have is great -- the coals come quick and fat and long-lasting.

Horse Chestnut and Buckeye are both the same thing: Buckeye, the Ohio state tree, and there is also a California buckeye. The genus is Aesculus, referring to the glycoside esculin.

< I've only been into primitive skills since last May. Buckeye is a tree, by the way, not a little plant like mullein.

Understood

>

I don't know, but I would rather assume that he collected saplings which typically need little preparation of shaving, are of the right diameter and may grow straight for about 2 ft. length. There is a brief description in ISHI, The Last Indian, or Yahi (?). As I recall, it only mentions the use of buckeye. I think there is also a picture of him using a long (3 ft. or so) spindle. Too bad there is none here in the east, i'd like to try it.

I have had great success with dry mullein collected in the fall, splitting larger and thicker wall stalk bases for fire board. It took me about 3 years to get all the pieces right.

AndrÈ,

I believe naturalist Christopher Nyerges gave common names for some Buckeye varieties as California Chestnut and Horse Chestnut. Benjamin Pressley pointed out that their scientific names could be found on the "Ethnobotany Cafe" website's databases. I checked and under Native American Medicinal Plants, found the following. Here's three listings - the first for California Buckeye and the second and third

for the horse chestnut. Notice the specific mention of Native American Indian usages for food, medicine and as a talisman. I can tell you that it looks like large nut with a smooth hard brown shell. Kind of like a giant Filbert in appearance Hope this helps.

Chris Smith

This reply kind of covers an earlier thread about fish poison and concerns the California Buckeye, *Aesculus californica*. Local natives did use the buckeye as a backup to acorn, preparing it in much the same way. So California buckeye is reputed to be edible when leached, though I will let you know after the ones I have gathered have dried and I prepare some. It is supposed to have needed more leaching than acorn and did not taste as good. Another use of the buckeye by the locals was

as a fish poison. They would either make a dam or use a natural deep hole where fish were likely to be, and dump in a basket of ground buckeye. This was supposed to have knocked them out and they floated to the surface for easier gathering. BTW, in my area, the California buckeye produces an enormous fruit compared to the eastern variety, perhaps 2-3" in diameter. I have also heard that the nectar from the flower is poisonous to bees. Again, I cannot personally vouch for this. Hope this is new information.

Hey, I can help on this one, finally (living currently in Dayton, Ohio)! Buckeye, *Aesculus glabra*, a medium-size tree with a range from the Alleghenies to central Texas. Produces a foul-smelling odor when its leaves, bark or twigs are crushed, hence the nickname "fetid buckeye." Oh, and the chestnut-like seed is poisonous, so don't eat 'em. Wood is

fairly light and easy to carve, but fairly scarce these days.

Mullein is pretty abundant here in the southeastern U.S. I could mail you a couple of straight stalks, I have that are well seasoned for you to play around with, if you like.

Also, Here are some references to the Ishi books I know about. Sorry, I don't have an ISBN:

Ishi, In Two Worlds by Theodora Kroeber

Ishi, Last of His Tribe by Theodora Kroeber

Ishi, The Last Yahi by Theodora Kroeber

They can be ordered from: B.O.S.S., P.O. Box 1590, Boulder, CO 80306,  
Phone: (303) 444-9779

In a message dated 96-12-28 11:39:37 EST, Andre' writes:

<< Hi John, sure like to know your conclusions on the dimensions of the pieces and other details. I have a hard time finding straight Mullen

(Verbascum spp) here in the north.

Also, do you have a reference to that Ishi book you are mentioning?

Thanks for sharing, great stuff! >>

I use Mullein fire board and stalk. Suitable spindle pieces are about 10 to 20 % of all stalks from what I have found, so keep looking. The business end (bottom end of stalk) of the spindle is 3/8" to 7/16" in dia. and the stalk is 20 to 28 inches long. Often you will find a suitably straight piece somewhere along a longer stalk so don't just look for 20 to 30 inch stalks, you'll be looking forever. I have been successful with stalks 18" long, but the longer, the better (easier). Split mullein stalks as fire board can be any diameter larger than at least 1.25 to 1.5 times the diameter of the spindle. The thicker the wall of the stalk you use for the fire board, the better. There is more "meat" in the material and therefore less chance of pushing or burning through before you get a coal going. Sometimes you can find one stalk which is tall enough to get both parts from but more often you need to use two separate stalks. Larger stalks serve best as boards, thinner (but not too thin) and straight stalks serve as spindles. The pith should be left in the board as it helps condition the spindle and I think helps produce a good powder reservoir to heat up to ignition (smouldering coal) temperature. Start the spindle circle in it nearer one side or the other then cut the notch. Successive "holes" can be formed down in a row spaced every 3/4 inch or so. A used stalk board looks like a spent cap-gun roll of caps. Lastly, I use a piece of flattened wood (a wood fire board would work fine) to place the mullein fire board on top of and which the powder coal forms on. No tinder is necessary. Actually, tinder at the face of the notch packs and suffocates the coal powder. Too much pressure and too slow twirling of the spindle are two common errors which will defeat success. Take your time in developing calluses on your hands as well. You will no doubt get blisters and have to lance them, let them heal a bit and start again when they dry. Keep on trying. Good luck. Glad to help out.

I suppose I mentioned that I had just gotten my first fire with a  
cattail in my intro, so I'll take a poke at this.

The key seems to be speed rather than downward pressure. Cattail  
doesn't have great strength, and power is my typical MO (Doesn't fit?  
get a bigger hammer!) I probably broke three shafts before I figured it  
out. Learning on cattail is a great way to perfect form. I was  
surprised at how fast it drills through a fireboard of cedar though, and  
recommend a little bit thicker board than usual. Apparently that outer  
layer is quite hard. I wish you luck, and would love to hear of any  
successes and frustrations as you go. I practiced this for a long time  
before I got a fire - probably 10 - 15 tries. Usually I decide that  
whoever told me a particluar weed would light up an ember was crazy  
after about three or four unsuccessful tries.

See you in a week or two,  
Kevin

Some one posted a success with a cattail stalk (for fire making that is) a  
day or two ago.

I'm having some difficulty with this technique. Could some one post some  
info.

Whats some tried and proven fire boards (woods) that work with these  
stalks?

Even when dry, the stalks seem awfully flimsy to me. (sort of like a straw,  
and as soon as your stalk gets a kink in it, it folds over.) There is more  
than one species so maybe the flower stalks of one species are more "woody"  
than the other?

What diameter works best?

Kelly Harlton

PS

The Idea of making fire with cattails excites me because there are not a  
lot of woody stemmed weeds to use for a hand drill in my area. recently I  
had a buddy (he lurks on this list also), send me mullein which works  
great! Now I'm jealous that we dont have any of this wonderful plant in my  
area.

I've seen a video of Ron Jamison using a cattail stalk on a clematis fireboard. In my part of the country, teasel stalks are abundant and work better than mullein. I like to use a Basswood (Linden) fireboard.

Here's another neat trick suggested by McPherson; put a small notch at the top of your handdrill. Then take a small piece of cordage, say 10", and put a small loop in each end. Lay the middle of the cordage in the notch with the two loops hanging down alongside the drill. Place your thumbs in the loops and position your hands as usual for rotating the drill. The loops provide a means of constant downward pressure so you do not have to worry about stopping at the end of a downward stroke and repositioning your hands. This is a great way to get your first fire with a handdrill and also helps in a survival situation if you can only find a short drill. The strength and quantity demands are much more modest than for a bow drill set.

I would second this request. My experience with cattail is that it just is not strong enough to withstand use for friction fire making (handdrill). I've heard of goldenrod being used also but have much the same problem around here with that. Essentially as soon as downward

pressure is applied it either a)disintegrates or b)bends and falls apart. I know mullien that is more than a year old will do this also but this stuff is fresh and dried from the previous summer. I'm also using the largest stalks I can find (around 3/8 to 1/2 inch at the base). A friend in Virginia has told me that mullien out there is to "thin walled" to work which has been contrary to my experience with good ol' Wisconsin Mullien. Maybe this is just a regional difference.

Whether fire by friction is by bowdrill, handdrill, fire saw or fire thong, the theoretical principle of what makes this work is very useful to know. I will try to put words on something that anyone who has practised these skills for a long time tends to know by "feeling".

When wood is rubbed against wood, one of the materials is harder than the other. Even when the wood for fireboard and spindle are of the same wood, the spindle is harder than the fireboard in the sense that the fibers are cross grain rather than with the grain. Thus, basic theoretical principle #1, the harder wood grinds wood dust from the softer wood. Of course, some wood is ground from the harder of the two wood pieces too, but much more from the softer of the two, in this case the fireboard. Principle #2, is that when wood grinds hard enough, wood dust is created in the form of sawdust. Principle #3, when wood grinds hard enough and/or fast enough, heat is generated and the sawdust starts smoking and charring.

Now, the following is very important. Usually, sawdust is light, and when you rub wood, the sawdust moves away from the friction area and thus cools off, and new wood is rubbed which creates new sawdust which is cooler. This means that theoretically, you can do this forever and never obtain a coal or a fire.

Principle #4, then, is that to obtain a coal, YOU MUST RUB WOOD OVER AND OVER ON THE SAME SAWDUST. This is why you cut a notch in the fireboard, for instance. The hot sawdust gets wedged in the notch, preventing it from moving away from the friction area, and you are then rubbing over and over on the same sawdust and a coal will get created at that exact spot.

The coal then spreads to the remaining sawdust, making it grow, creating sufficient heat to flame tinder.

Principle #5, weight. Ususally it is not sufficient to have the burnt sawdust wedged in between a crack. There is also a weight consideration. The pile of sawdust must be big enough and therefore heavy enough to prevent the newly formed sawdust from moving it and cooling it off.

The 6th principle deals with the fact that for fire to occur, there must be sufficient combustible material. If there is not enough wood sawdust around the forming coal, it will not gather the momentum necessary to grow to usable size. Just like a fire can't be built with a match and a single stick, a coal cannot form if there isn't enough burnt sawdust around it.

Finally, 7th principle, a fire needs air to complete the heat-combustible material-oxygen trio necessary for ignition. This is much less important in practice because the small wood sawdust balls under a microscope reveal plenty of air space between them.

Now we can look at practical questions. Can a bowdrill fire be made without a notch? Yes, it makes sense now, doesn't it? Just keep drilling long enough and hard enough so that the burnt wood sawdust pile around the friction area gets big and heavy enough not to move as you keep drilling. I have obtained up to 5 coals at once all around the drilling area this way.

What about the fire saw. Well, as the saw traverses the bamboo half round board, burnt wood dust accumulates underneath and you are rubbing back and forth on the same pile of wood dust which can't move because it's stuck underneath the board! As in bow drill and hand drill, it is now obvious (or should be) that filling the notch with tinder will prevent a coal from forming...

Fire thong works on exactly the same principle. The thong goes underneath a piece of wood which is split open about 1/4 inch, and burnt wood sawdust accumulates above the thong and gets wedged in that split and can't move. Once the crack is full, the thong rubs back and forth against the same wood powder and the coal ignites there.

The fireplow technique is harder to understand and doesn't work everytime because it relies on brute strength to generate sufficient heat in the pile of wood dust to ignite a coal at a random spot in the pile. Since this technique cannot be duplicated precisely the same way everytime, it is hard to come to a conclusion about what is happening but I think it is this. As the pile of wooddust at the bottom of the plow gets heavy enough and cannot move, the heat transfer from the friction area ignites a coal on the bottom edge of the pile, which usually manifests itself as a coal on top of the pile when it is accidentally hit by the grinding stick. Note that I have tried making artificial fireplows by tying sticks to my jigsaw blade and was not able to produce fire! The principles are not respected accurately in this technique, and probably a random crack between the dust pile and the plow board must permit the formation of the coal. Scratch me!

As for the new "fire hole" technique, there must be a crack in one of the pieces of wood in which burnt wood dust can accumulate. It will most probably look like an upside down fire saw. Can't get away from the principles if it is to work. Looking forward to Ben's post on this.

Hope this helps...

Barry Keagan commented in his article on bow drill strings that even if he was successful at

a hand drill fire with hickory (which means he has practiced a hell of a lot) "I reached MY

physical limitations when trying with a damp mullein stalk". I reached MY physical limitations much earlier than Barry, and I agree with him: very rarely are conditions

so  
perfect as to make a hand drill fire in nature (here in the boreal forest at least).  
Bow  
drill is much easier, and success is always guaranteed: I have done it at -40  
degrees and  
also in pouring rain. However, like Barry says: the hand drill fire is the fastest  
way to  
obtain fire, and it's good to know for those occasions where it will save you the  
time to  
go make bow etc. Now this comment might not apply in the south where it is warm and  
dry.

>  
> 2) Your description of repeated friction over the same charred sawdust makes  
> sense, but do you have an explanation for why the coal (most) often appears  
> some distance away from the board and notch?

The explanation is that even when the wood dust pile is not quite heavy enough to  
hold in  
place, but partly so, sufficient friction occurs to form the small coal anyway before  
the  
new dust forces the pile (including the coal) over. You don't notice this because of  
all  
the smoke from the grinding of the hard surface on the soft surface. If your coal  
appears  
far away from the center, you are probably drilling too much for nothing- your coal  
was  
already formed several seconds ago. When you go for speed records on bow drill you  
learn  
precisely when the coal has formed, and that is always where the rub is. Also, when  
you  
don't quite achieve a coal, you notice the black char which almost made a coal right  
next  
to the rubbing spot. Try a thinner board so the notch fills up faster and making the  
coal  
as fast as possible- under 10 seconds is fairly easy with cedar- under 4 seconds is  
possible. This will teach you exactly when the coal forms faster than any  
instructions.

>  
>It seems to me that the notch  
> also helps direct the heat, and/or perhaps the spindle creates a bit of air  
> current to help the coal breath to life.

Both of these assumptions are logical and are certainly true to a certain extent.

> 3) On another technique which I thought was the fire hole, Tom Brown gives  
> the following description on using burdock or mullein: "Just twirl the

Sorry, this description makes no sense to me either. Maybe one of us can contact Tom  
and

ask him to clarify this.

> 5) Other hand spindle materials include evening primrose stalk, ornamental  
> honeysuckle (shrub) shoots though they tend to split, and elderberry (limited  
> success due to thin wall on the specimens I have.

I too have tried evening primrose (Oenothera spp.) and have also had success with  
burdock  
(Arctium spp.) on cedar, which is fairly easy. Never tried elderberry, but I've got  
lots  
here so I'll let you know. Maybe others could complete the list of hand drill  
materials.

Another question? Anybody else notice that friction fire sometimes does not work  
because  
the wood is TOO DRY? And does anybody know why the wood sometimes squeaks like a  
tormented  
pig?

Hope this helps,

Andr 

Dear Andre' & PSG's:

Great post on Fire by friction theory as well as Benjamin Pressley's on the fire saw! I am anxious to try it.

By the way, I tried cattail spindle (7/16", 11.2mm) & willow board based on someone's recent post. Works great! I have a few questions and comments on the subject though.

1) I imagine that finding cattail which is dry and ready to start fire immediately after picking might be difficult. I would think that the plant would have to be in a spot which is dried up, otherwise the stalk will be wicking up water and will require a couple days drying time (provided you can find a dry place to dry it in, like your living room). Any comment?

2) Your description of repeated friction over the same charred sawdust makes sense, but do you have an explanation for why the coal (most) often appears some distance away from the board and notch? It seems to me that the notch also helps direct the heat, and/or perhaps the spindle creates a bit of air current to help the coal breath to life.

3) On another technique which I thought was the fire hole, Tom Brown gives the following description on using burdock or mullein: "Just twirl the spindle until it burns down to the pith, then carve the pith out at an angle just beneath the hole. The hot dust then falls down inside and collects in the hollowed receptacle near one end. Finally, the stalk is turned upside down and the coal tapped onto the tinder."

Well, I understand the last sentence, but the setup of the rest of the board escapes me. Any better explanations?

4) I have also found split sumac branches to be a good fire board material or a split mullein stalk (with pith, as posted previously). Drilling from the split (flat) side leaves the rounded side down, curving away toward the center of the spindle and allows sawdust to seek its own density conducive to good heat gain and air entrainment. This could also require more sawdust to build up and make a coal, so depending on the diameter and type of material (how fast it wears) you can build up the bottom of notch with just a bit of tinder.

5) Other hand spindle materials include evening primrose stalk, ornamental honeysuckle (shrub) shoots though they tend to split, and elderberry (limited success due to thin wall on the specimens I have).

Hi Charles,

Good to have you aboard. Please say hi to Fire Hawk for me. For anyone interested Fire Hawk is one person who has definately mastered the cattail hand drill. Possibly Charles can relay some info from Fire Hawk about cattail hand drill.

Walk in Balance,

Bob Barr

Awhile back there was a discussion about putting a notch in the top of the hand drill and draping a string over it with a thumb loop at each end. You do the normal spinning with the hands, but the string looped over the top keeps your hands at the same spot on the spindle and allows you to still get good downward pressure. I use this technique when my hand drill set is less than optimal. The added aid of the string gives me just enough help, usually, to get a coal.

It is an excellent technique to prepare for learning the hand drill. It gives you confidence that you can get a coal by spinning with your hands. Once you get consistent with this, take away the string and you should be able to get a real hand drill going with no trouble.

BTW, My hand drills are typically pencil sized in diameter, and about 2+ feet long. Here is a tip for success: spin to fill up the notch with dust. Take a break and rest. Now all you need to do is ignite the dust by dedicating yourself to spin as fast as you can for about 15 to 20 seconds. A word of warning to first timers, as soon as you stop spinning,

remove the spindle and start waving your hand back and forth over the coal in the notch while you catch your breath. I have seen the tiniest, wispiest coals survive and grow, as long as you start fanning them immediately. Be patient, keep fanning, stop for a second and check for wisps of smoke. If your still see smoke after fanning those, first few seconds after removing the spindle, you have a coal and you just need to keep feeding it with air.

Once I catch my breath, I prefer to start blowing a long gentle stream of air on the coal. If you see dust flying out of the notch you are blowing too hard, otherwise blow long and steady. I never remove a coal from the notch until I see the red glow of the coal spreading strongly throughout the coal.

Again, I find the key to success is to fan the coal immediately upon removal of the spindle. Many times in the past I would remove the spindle and still see smoke but would stare dumbly at it for a second before feeding it with air. I probably lost quite a few potential coals while I was learning because of the time delay. Now that I know better, I give it lots of air first, before I try and decide if I really have a coal or not.

The beauty of this string enhancement is that the string does not have to be very strong. Natural materials are quite adequate, even when they are but twine thickness. Plus, the cordage needed is only about 12-14" long. I have a much easier time getting a fire going with this technique during "naked survival". The strength demands for a bow drill string, or less than perfect hand drill materials use to keep me from getting a fire quickly under, "no knife, no cordage" conditions. Now, this technique solves a lot of the problems by eliminating the trouble spots of the other techniques.

P.S. It is not as hard or as difficult as you think, for you first timers. Get dust in the notch, catch your breath, then spin as fast as you can for a slow count to 20. I think you will surprise yourself.

Bo Gulledge wrote:

>

an excellent post on hand drill tricks.

We want more, more, MORE! Thanks Bo!

Believe it or not, I don't have much experience with hand drill. Wood and plants here are always so wet that they just don't seem to work for me in real situations. Also, since I'm into realistic survival I'm always sure that I can get bowdrill fire with a piece of string made from laces, belts, etc. so it got me disinterested in the hand drill a long time ago. But now you've got me interested, because obviously a hand drill is faster, so I'm all ears and ready to learn more.

Questions:

1. I often find that mullein stalks and cattail stalks have the problem of falling apart as I spin. They develop a small crack in the end and then split open. Any ideas?

2. The wood dust which falls into the notch is often not dark like in the bow drill because of lack of speed. Any ideas?

3. Is it ever possible to find a dry cattail stalk and use it "as is"? I haven't been able to.

4. Since the drill is so much smaller in diameter, do you cut the notch any differently so there is as much air access and as much room for the coal to grow?

5. What materials will work other than mullein, cattail, evening primrose (*Oenothera* spp.), and burdock (*Arctium* spp.)? What about for fireboard (I've only tried cedar with above)? Could you give us the easiest choices in order of importance?

> A word of warning to first timers, as soon as you stop spinning,  
> remove the spindle and start waving your hand back and forth over the coal  
> in the notch while you catch your breath.

That's a great trick, I use it all the time too! It's very very important to do this.

I have seen the tiniest,  
> wispiest coals survive and grow, as long as you start fanning them  
> immediately.

Me too, I've seen coals where I was sure there couldn't be.

>  
> Once I catch my breath, I prefer to start blowing a long gentle stream of  
> air on the coal. If you see dust flying out of the notch you are blowing  
> too hard, otherwise blow long and steady. I never remove a coal from the  
> notch until I see the red glow of the coal spreading strongly throughout  
> the coal.

More tricks:

1. Once the coal is fairly big, the wood dust pile seems to stick together. Tap the fireboard slightly on the side opposite the coal, to loosen it from the board before moving it to the tinder nest. If you don't do this, the coal will sometimes break apart into two or many smaller coals and you can lose the fire.

2. Dump the extra powder which is all around the drill hole on top of the coal pile at this point. This gives you just that little wee extra edge in getting the tinder to light.

3. Once you catch your breath and stop shaking like a leaf, move the coal (which is on a piece of bark) to a position above your head, and blow from below it at an angle. That way you avoid breathing smoke and this prevents coughing at the coal and losing it.

>

Again, thanks Bo for a great post, and looking forward to hearing more about this from you or others. Let's not forget that fire is by far the most useful skill to master.

Andre

Here are some basic answers to your post. I do not have extensive knowledge, but have had to make do with a lot of substandard handdrills. It has been my experience also that most items are too wet to use, but I have been able to start handdrill fires with wet parts on a misty day.

1. I have found that if you wrap (using sinew or cordage) the length of the handdrill (always leaving 2" free as a burning surface) it will help to prevent some cracking and splitting.
2. I normally heat up the board by spinning quickly with not a lot of downward pressure. In this way the board will produce dark dust. This also has the added advantage of partially drying up the board and shaft.
3. Have not had much experience with cattail, always too wet to work with right away.
4. The notch I normaaly cut in the board is about 60 degrees. If it is too large, then the dust does ot seem to be able to ignite. If it is too small the dust produced will actually smother the coal.
5. This has been an area of work with some of the earthlodge group. some of the items wee have tried are: reed grass, staghorn sumac, willow, and milkweed.

Even more impressive is to do the same thing but move your arm vigorously in a large full circle. I have done this at dusk in front of hundreds of people in large council rings, and it is very impressive, because at first you see a bit of smoke, then lots of smoke, and because of the dark, you see a few sparks, a ring of sparks, and eventually a ring of fire which you maintain as long as you can before throwing it on the awaiting gas drenched bonfire which blows up into flame. Theatrics!

Following is a cross post from the trackers list. I would like to see what experiences anyone on this list has with the floating technique for the hand drill. I can get dust with it but I cannot ignite the coal with it.

On Tue, 10 Sep 1996, Terry Morse wrote:

```
> >This is a technique to spin and apply downward pressure as your hands

>
> >Bo Gullede
>
> Bo:
>
> Did I miss your description of how to "float," or are you preparing to
> post it? :-)
>
```

I knew some inquiring mind was going to ask me this so I guess I will give it a shot. :-)

Picture a bowl that has a radius equal to the distance from the tip of your fingers to the heel of your palm with your hand held stiff and flat. Now, picture a hole in the center of the bowl through which you insert the spindle of your hand drill.

Your hands are at at about a 90 degree angle to one another. The fingers of one hand point down 45 degrees and the fingers of the other hand point up 45 degrees: (be gentle with me, this is one of my first attempts at ascii art ;-) )

The motion is one of having your hands exchange their orientation to one another as though the knife edge side of your hand is following the curve of that imaginary bowl I was talking about.

What makes this work is at least one hand is always pushing down as it spins. The action of the up motion of the hands even allows you to work your hands up the spindle while still generating downward pressure. Or, you can "float" with your hands moving neither up nor down the spindle.

Play with just doing it lightly and then figure out the dynamics of how to add more downward pressure.

Ask me questions if this whole description makes no sense!  
Please give some feedback on this description so we can generate a workable description for future generations ;-)

Since we're reminiscing here. I once did a demo with a bunch of Girl Scouts. I transferred the ember to the tinder bundle and had doubters in the audience. It was a breezy day. I helfd the tinder bundle high over my head and the bundle suddenly burst into flames. Then it was total silence as they thought surely I was magic! Fun moments!

I saw Charles Worsham light the easiest fire I have ever seen made using a floating technique with a cottonwood fire board and horsetweed spindle. He made to runs down the stalk however- a pressure run and final speed run to ignite the coal. So far I am only working on developing the technique with a little training kit I made with a dowel and a chunk of oak. There is great potential here!

Mark

I have found that notch geometry is critical. I have developed a system that automatically scales the notch to the board and drill (Don't laugh, I have an engineering background and the method seems overly technical. But once you try it, it works itself.) All marking can be done with your knife. For simplicity, lets assume the fireboard is rectangular with rather short ends and rather long sides, but the technique works with other shapes.

1. I like to use a drill that is approximately the diameter of my little finger and a board the thickness equal to the width of the nail of my little finger.
2. Start by placing the prepared drill end at the edge of the fireboard somewhere along its length. Place a mark on the other side of the drill so that the mark is one drill diameter from the side edge. This distance will probably be shorter than from the mark to the other edge of the board. All subsequent marks and notch cuts will be made in this shorter area. Note: when using mullien or teasel it is a good idea to scrape the crusty outer skin off the end that contacts the board.
3. Press the drill into the board to make a circular imprint (the fireboard wood should be soft enough to indent when pressed with your fingernail, I like willow or basswood). Use you knife to dig a shallow disk shaped impression.
4. Place the drill in the impression and twirl to burn in a ring shaped hole no more than 1/8 inch deep. This assumes you have a hollow type drill material, but I have used the technique successfully with a solid willow hand drill.
5. With your knife, scribe a line all the way around the board, tangent to the burn ring and parallel to the short ends of the board. This is line 1. (later, once you see how this all works, you will only have to go half way around)
6. Scribe another line the same way on the other side of the ring. You now have two parallel lines on each side of the ring. This is line 2.
7. Scribe a third line around the board, passing through the center of the ring. You now have three parallel lines. This is line 3.
8. Use your knife blade to measure the distance from the nearest side edge of the board to the center of the ring. Turn the board over and place a mark this distance from the same edge on the bottom of the board. This mark is now under the center of the ring on the other side, and intersects the middle scribed line. Let's call this point A.
9. Scribe a line from point A to the intersection of line 1 and the bottom edge of the board. This intersection is point B.
10. Scribe a line from point B, up the thickness of the board to the top of the board and on to the intersection of line 3 and the nearest edge of the ring. This intersection is point C. The line should be the shortest distance from point B to point C. If you look from the edge of the board toward the ring, the line will look diagonal about 45 degrees as it runs

from B to C.

11. Scribe a line from point A to the intersection of line 2 and the bottom edge of the board. This is point D.

12. Scribe a line from point D, up the thickness of the board to the top of the board and on to point C. If you look at the board from the edge, you will see that you have now scribed a diamond shaped figure wrapping from the bottom to the top of the board. The first time it may help you to visualize this by coloring in the diamond with a pencil.

13. With your knife, chop out a small wedge of wood from the bottom edge of the board into the center of the diamond (just two straight v-cuts). Make the wedge bigger until it expands to the form of the diamond. You will now have a notch that flares down and out as described in some books but scaled precisely for your materials. Make the notch extend into the burn ring at point C until you hit the inner, unburned diameter of the ring.

Now the notch is complete and you can insert the drill and try for the coal. As the drill burns into the board, an ever widening hole forms into the notched out area. The geometry of the notch compacts the dust and reflects the heat toward the center of the dust pile.

This explanation will seem hopelessly complicated unless you do it as you read. Even then it may be confusing without a drawing. Let me know. I have been very successful teaching others to do it by example but this is my first attempt at a description. I would like to hear your comments.

Rob Chatburn

Rob, you are absolutely brilliant! Your way of calculating the notch size proportionally to the size of the drill and thickness of the board, is the best I have ever seen anywhere. I wish I had thought of that! I can no longer imagine teaching it in any other way, and I've been trying for years to devise a system to explain my notch which is "by feeling" exactly as you describe. I've tried drawing proportions, pie wedges and everything else, but you've just described it in a way which has only one word to describe it: brilliant. Thanks so much for sharing this with us.

Maybe I can help with the description which is a bit hard to follow, since I did my doctorate on how to write clear instructions for survival skills. If you accept my interference, I would be honored to write up the instructions for your use and for publication purposes. Let me know if you accept this offer.

I think cottowood is (Populus spp.), but what species is "horsetweed"?  
Never heard of a plant by that name...

In a message dated 97-01-21 16:03:10 EST, Andre wrote:

<<

1. I often find that mullein stalks and cattail stalks have the problem of falling apart as I spin. They develop a small crack in the end and then split open. Any ideas?>

I find most times it's because the stalks are too old. That is, collected too late in the season. Try collecting as so as they die & brown.

2. The wood dust which falls into the notch is often not dark like in the bow drill because of lack of speed. Any ideas?

I often get a horizontal dark streak in the dust mound. I don't believe you will ever get a completely dark dust mound. As you have said, it takes repeated heating passes over the same dust to char and coal. What do you get when you stop short of a coal using a bow drill? It could also have to do with material hardness, in producing dust more readily and not forming a coal as opposed to "wood" branches which need more energy (and therefore more heat) to form dust. So with bow drilling, you are further along with more energy in producing a coal.

3. Is it ever possible to find a dry cattail stalk and use it "as is"? I haven't been able to.

I asked this Q a couple of weeks ago. I think the answer is yes but only if the cattail roots are dry with no water to wick. But when are you going to find that?!

4. Since the drill is so much smaller in diameter, do you cut the notch any differently so there is as much air access and as much room for the coal to grow?

No, the notch is cut the same width/pie segment as for bow dirll. However, because your movement requires your body to travel downward, I find that the drill is may be difficult to keep centered in the notch. It might help if the notch is cut a bit to the left or right of center when viewed facing the notch, depending on how your body naturally "curves" on the downward travel.

5. What materials will work other than mullein, cattail, evening primrose (*Oenothera* spp.), and burdock (*Arctium* spp.)? What about for fireboard (I've only tried cedar with above)? Could you give us the easiest choices in order of importance?

>>

I believe that mullein is the best. Someone recently posted that teasel was easier than mullein. I've yet to get some & try.

I have had repeated easy success with cattail using willow fire board. Not so good using mullein. Some success with Staghorn Sumac & mullein & primrose.

Another technique I have found useful is to breath in as you spin down the drill. Exhale as you return to the top and repeat. No getting out-of-breath, only burning arms or hands!

I always use the one-kneeling position as opposed to sitting, although sitting has worked a couple of times that I've tried.

Sorry Andre',

Cottonwood probably is not a common tree in your area. I know it doesn't grow here in northern WI. Scientific name Populus deltoides.

Horseweed is mystery. I don't know much about it. It doesn't grow in the north. Scientific name Erigeron canadensis (with a name like that one would think it might be in your back yard :-)). It is a tall stalk with a bushy top. Tends to grow in "waste areas". Works well from what I've seen. I found something around here that was similar and I was excited but it turned out to have a hollow stalk.

That's about all I know,

Mark

<<  
What makes this work is at least one hand is always pushing down as it spins. The action of the up motion of the hands even allows you to work your hands up the spindle while still generating downward pressure. Or, you can "float" with your hands moving neither up nor down the spindle.  
>>

Could it be that it is better using a string so that there is no need to stop and re-start a pass at the top of the stalk? Constant pressure while continuously spinning sounds verry effective. I am anxious to try it... could someone just email me about 48 hours of free time?

The best fireboard for mullein is another split mullein stalk. Just start the "hole" on the flat inner half, carve the notch and finish it off in dust and a coal!

The stalk should be the lower part of the same stalk or a different stalk of a larger diam.

Yes, but I have only done it once or twice so I cannot say if some modifications might apply. None are obvious to me at this time. And I have seen others recommend this type of flared-out notch for bow drills so scaling it as I describe seems to make sense. I have made dozens of hand drill fires with this technique and since mastering it, have not practiced much with the bow drill. This is probably a mistake as the proper materials for a hand drill may not always be available.

Maybe you could experiment and let us know.

Rob Chatburn

This is fascinating! I have seen a fireboard made by lashing two unsplit pieces of mullein together, but I could not see exactly where the dust would go as there was no notch (perhaps through the crack between the two stalks). I have not had any success with this. Can you give us more details?

I have been told that a basswood drill in a paw paw fireboard works like rubbing a match against a rock! Can't find much paw paw around here so cannot verify. Also, I think breathing is very important (not just because I'm a respiratory therapist ;-). Most people tend to hold their breath unconsciously when applying muscular effort. I like to breathe out as I work down the drill and try to exhale through slightly pursed lips along the drill. I am not sure but it seems to feed the coal after it starts smoking a lot.

Sorry, Merv, for the record it cannot be Equisetum spp if it is used for starting fires. I know Equisetum and it is much too soft for fire drills. You're right about pot scrubbing. Equisetum has a substance

called Silica in it which acts as a good polishing agent. Equisetum also makes a great fingernail file for all you gentlemen and ladies who like to keep their hand and feet ends neat and trim.

In a message dated 97-01-22 23:05:06 EST, you write:

<< I like to breathe out as I work down the drill and try to exhale through slightly pursed lips along the drill. I am not sure but it seems to feed the coal after it starts smoking a lot.

>>

Rob:

I find that breathing in on the downstroke helps make me more rigid by inflating my lungs. I am a lean 130 lbs, 5''-7" and need all the help I can get in using muscle efficiently. Breathing out on the downstroke lessens my internal pressure and therefore stability which doesn't help my drilling.

But as you point out, breathing is soo important. It is easy to forget that every breath, or every one lost is beneficial or missed, especially when additional work is required of muscles. A fire won't burn without O2, and neither will our glycogen. I am amazed at how fast our biochemical reactions take place.

This is fascinating! I have seen a fireboard made by lashing two unsplit pieces of mullein together, but I could not see exactly where the dust would go as there was no notch (perhaps through the crack between the two

stalks). I have not had any success with this. Can you give us more details?  
>>

I have no knowledge of using two stalks lashed together. But in any patch of mullein, pick some straight stalks of 3/8 to 7/16" diam (Business end, bottom of stalk) and pick any other with a larger diam. Usually near the bottom, or possibly the base portion of the drill stalk, farther down. Using a short segment of this lower stalk (anything long enough so you can get your foot and spindle onto) Split it in half to make a Board. The inner split portion must be the width of the business end of the stalk/hand drill with at least 1/4" to spare. Start an indentation by spinning lightly with the drill into the pith (curved side down). Carve a "typical" notch, and finish it off by spinning the hand drill again and get your coal. NO TINDER NECESSARY! the drilling creates a large cache of sawdust which grows the coal. Transfer the hefty coal to tinder/grass for easy fire.

A well-used fire board can have notches/drill burn discs quite closely spaced. Making a notch, the mullein cuts well under a thin sharp knife.

The first few times I got a fcoal using a mullein fireboard, I didn't cut a notch. It was very happenstance that in burning down through the pith the spindle burned through at just the right time and temperature to kindle cattail down. That was not a reliable technique at all.

If the end of the drill stalk should burnish into a burn glaze, simply pop out the glaze disc to reveal a fresh friction surface.

Good tip John. And it makes physiologic sense because you use your  
intercostal muscles when you breathe in, while exhalation is usually  
passive, requiring no muscular tension. I'll see if it helps the next time  
I try to teach people with smaller thoraxes, like maybe kids. When I  
breathe out through pursed lips, my exhalation requires muscular effort  
too, so maybe I'm getting the same effect you describe.

John Waltz described a great technique for using mullein stalks as both hand drill and fireboard. This is great! Saves time and energy. And a stalk would be much easier to notch with an expedient stone implement than even the softest tree wood. Has anyone tried this with teasel? Wonder why none of the major textbooks on survival mention this? (Tom Elpel's book does mention yucca as both drill and fireboard)

Bill's mention of scrounged modern materials for fire starters he found out about as a kid, caught me at a similar point in my remembrances. I had been raised in and around the aluminum and magnesium foundry business. My Dad always had machine shops at these and I learned to locate magnesium turnings under the lathes whenever he'd been doing a run of magnesium castings. 0000 Steel wool tinder on massive steroids. Light (pun intended) to pack in a pouch. While you're out gleaning the dental labs for epoxy firestarter putty Bill, you might keep an eye out for metal foundries. Serious fun (I'm thinking of your son Hans here, not for us old guys...yeah...that could happen...sure).

Chris

Pascal Chauvaux of France sent me a message in french stating the name of the material which makes up the flint side of the magnesium striker. It's called ferrocium and it's the same material which is in modern lighters. Thanks Pascal!

Now all of you pyromaniacs out there get to find out what kind of a tease I can be! If anyone can start a fire by striking a knife against the small piece of ferrocium inside an empty BIC lighter and a paper tissue (It can be done!), then I will post how to do it much, much more easily!

Good luck,

AndrÈ

Just so you won't forget that this is ALSO the magnesium striker list,  
(our guidelines permit modern survival subjects too) I'll post the  
following information I've discovered over the years on this subject.

A magnesium striker is as far as I'm concerned the most fantastic  
emergency fire lighting device in existence. I have a small piece about  
1 inch long by 1/4 inch wide which is an integral part of my key chain.  
Helluvalot luckier than a rabbit's foot in a survival situation, that's  
for sure!

Now for using it- the instructions that come on the package suck. Try  
these instead:

1. SCRAPE A PILE OF MAGNESIUM SHAVINGS onto a dry and solid surface.  
Use the base (so you won't ruin your blade) of your knife blade at a 90  
degree angle to the magnesium. The size of the pile depends on the  
quality of the tinder; with the best, you can even skip this step. If  
your striker does not have a magnesium side, slowly scrape a pile of  
shavings directly from the flint side.
2. PLACE FINE TINDER in a semi-circle around and especially on top of  
the pile of magnesium shavings.
3. HOLD THE STRIKER VERY FIRMLY SO IT TOUCHES YOUR WORKING SURFACE right  
next to the other side of the semi-circle where there is no tinder. The  
base of the striker must touch the pile of magnesium.
4. HOLD THE KNIFE BLADE AT A 90 DEGREE ANGLE TO THE STRIKER and as close  
to it's top as possible. Press the striker downward very hard.
5. SCRAPE HARD DOWNWARD WITH THE KNIFE ONCE ONLY, pressing the knife

blade hard into the striking surface.

This procedure throws the largest spark possible directly into the tinder pile for instantaneous combustion. I have started thousands of fires in the most miserable rainy conditions using this technique. It works. However, you must practice with your striker until you can light a kleenex on a table with one strike every time. Then, and only then, will your striker become a very valuable addition to your pocket gear.

The magnesium striker works when soaking wet, and never misfunctions.

Other tips I can share which I have developed over the years:

Tying a large object to the striker, such as many keys on a keyring or a good stout stick on a cord helps to hold the striker tightly while scraping with the knife.

I have sharpened the square base of my swiss army knife blade at an acute angle for the sole purpose of magnesium fire starting, so I don't ruin my actual blade when scraping.

If you have no knife, some types of sharpened keys, zipper tabs, belt buckles, metal plates from boot soles or other hard metal sometimes work.

Sharp hard rock flakes (such as produced when flintknapping) also work instead of a knife!

Make the size of the pile of magnesium shavings twice as large as you think you need. To light fine wood shavings directly in a rainstorm, you need at least a tablespoon of magnesium shavings.

The magnesium burns very very hot but for a very very short time. Make sure you have a lot of very fine tinder extremely close to the striking area.

Don't forget: practice this until your family and friends nickname you "Pyro". It is, in my opinion, one of the most important realistic survival skills.

Cheers to all you fellow pyromaniacs,

Andr 

Read something about the fire piston somewhere else but I checked the web site to be sure. I am not sure if it was in American Survival Magazine or somewhere else, looked but couldn't find it right off. One of the things that I remember is that the tinder was "picked" out and that it was now used to light cigarettes! I think that the author had traded for one made of palm. Actually it works like a diesel engine and similiar principles apply. You would need tight fitting to create the pressure needed to heat the air, also a sharp, quick stroke would probably be most

successful. I think that I might try this after the holidays, might have time then.

THE MAN to talk to on fire piston is my friend 'Mountain' Mel Deweese. He is pictured in the Woodsmoke videos doing this and I have personally seen him do it many times at our annual event, TRIBE Gathering. If you wish to contact 'Montain' Mel: Mel T. Deweese, 1825 Linden St., Grand Junction, CO 81503, Phone: 970-242-8507. If you want to see the Woodsmoke video you can order it from: WOODSMOKE, Richard & Linda Jamison, 11401 Willow Hill Dr., Sandy, UT 84092, Phone: 801-571-1790. The video is entitled "Fire III" and also covers fire saw, fire thong and fire plow, price is \$34.95+\$3.50 S&H. They also have a book that discusses it entitled "WOODSMOKE: Collected Writings on Ancient Living Skills" for \$15.95+\$1.50 S&H.

Fire piston requires a very tight piston with a handle that is quickly inserted into and removed from a chamber that contains it that also hold a tiny bit of tinder (Usually a type of palm frond tendrils). Done correctly the forcing of the air molecules are caused to compress so rapidly that you virtually achieve spontaneous combustion or at least a glowing ember. Japanese commonly use brass cylinders of this type for lighting cigarettes. Mel used one carved from Buffalo horn.

The airguns they are talking about are springpiston type airguns in which a large spring drives a piston in a cylinder with a small hole in it. That hole is directly in line with the barrel. I've noticed smoke in the barrel after firing many of them as they burn off piston lubrication. I'm not sure where or how one would place tinder where it wouldn't be fired out of the barrel.

For fire piston, "mountain" Mel Dewese is the only expert I know and he says he has only had success with tinder derived from a certain palm. I know that's a vague reference, I'll try to find out the exact name of the palm. In the meantime anyone who wishes to contact Mel, can contact him

at: Nature Knowledge, 1825 Linden St., Grand Junction, CO 81503, Phone:  
970-242-8507.

As far as flint & steel, I have only had success with charred material  
and an uncharred fungus from up in Canada that a friend of mine brought  
me at TRIBE Gathering. Amazing stuff. A small sliver catches a spark and  
it glows and glows. Maybe Andre remembers the name of the fungus I'm  
talking about. George Hedgepeth brought it with him that year you came  
to TRIBE Gathering.

I have been communicating with Wyatt Earl who wrote the article on fire piston and was asking him about tinder other than charred cloth. Our communications might interest some of you... here goes.

Howdy AndrÈ!

First, thank you so much for your generous and kind appraisal of my fire piston article. It was a lot of work but very fun.

I am glad that you brought up the question of the shredded bark tinder that was mentioned in the article. I was reporting what John Rowlands said he used but in all my years of experimentation on the subject of catching sparks I have never had any succes with the dry, finely shredded bark. In addition, no one who is into primitive tech. that I have talked to has indicated success either. Ditto for mouse or birdnests. I have only had success with charred material. The only thing I have seen that is uncharred that will catch and nurture a spark is a type of fungus that is sometimes found in birches or cherry trees and it is amazing to see.

Because of your question I am going to edit my article to indicate the above observations. I appreciate you input and look forward to further conversations as well. It sure would be fun to make a living writing things like that firepiston article.

Happy Holidays, Andre

Hi Wyatt,

You might like to know that I have finally identified that birch fungus you are talking about. It is sometimes called Chatoquin or Bearshit but the scientific name is Innonotus obliquus. It is indeed a fungus (at first I thought it was a disease) but it is a white rot fungus rather than a brown rot like most rots we usually see. This white rot attacks the wood lignum and cellulose differently than brown rot and is responsible for forming a material which is similar in many ways to charred cloth. I am still looking into this and trying to find other fungi or material botanically related to Innonotus to try them out. Maybe this will help you with the tinder issue and maybe you and others can help pursue this research further.

Innonotus was also used medicinally in Russia, one source mentioned that (can't remember off hand, but I did write it down somewhere).

For tinder, this stuff is indeed amazing. One very fine spark into it and you can't put it out! However, I've noticed that if it dries out too dry, it no longer works. Much testing still to be done...

Best regards,

AndrÈ

PS We've got a great primitive skills group with many very knowledgeable leaders, you are very invited to join us!

I haven't tried the air gun, but the fire piston goes back farther than that. Fire plow is basically a board that is rubbed vigorously with a a stick digging a trough into the board (hearth). The friction builds up heat and grinds hot wood particles that gather and form into an ember. I personally have not used this method yet though. I have used the fire saw, though. There are many variations of the fire saw. The most well

known is splitting a 4 foot length of bamboo lengthwise. Tinder is held in one half. The other half is driven into the ground and held against the chest or abdomen. The half holding the tinder is rubbed vigorously across the other until the wall breaks through with heated particles that are basically your ember that can be blown into a flame. It is really difficult to explain thoroughly in this medium. Also I must depart for now and I will address other variations soon.

I've been tinkering with making fire pistons, and still haven't got one to build up enough pressure yet. I made 2 so far, one out of oak, and one out of bambo. The bambo was oval, so I can't get the gasket on the piston to perfectly match. The oak one was drilled, and aside from being a little rough on the sides, still doesn't build up enuff pressure.

Do the walls have to be smooth, and completely greased? I'm using thread wrapped around the piston, and heavily greased with deer fat. I didn't grease the walls, just what it picked up from the piston. Next I'm going to try leather as the gasket, and will try greasing the walls.

Any one played with this? I've seen a web site with info on it

<http://www.geocities.com/collegedpark/4201/piston.html>

and have come to the conclusion that it needs to be precision made (not just whipped up in a few minutes as I have done so far). Any other info is appreciated!

>one out of bambo. The bambo was oval, so I can't get the gasket on the  
>piston to perfectly match.

I used to watch the 'Yards use the things. It blew my mind how fast they were able to get a fire started. I never made one but I do remember a few things about how they did it.

The bamboo was large, as I remember something like 3" in diameter. The interior of the tubes were almost polished. They didn't even look like bamboo. The hole was just above the segment line and the segment distances (as I remember) were around two feet. I can't remember if they had cut through one segment or not. I do remember that the tubes were long, as long as my rifle.

The piston appeared to be another piece of bamboo that had been shaved and fitted with a flapper valve on the bottom of the segment. The valve looked like an inert tube rubber. When the piston was withdrawn, the valve would open, when the tube was shoved against a tree or post (to start the fire), the valve would close, sealing in the air.

When I first saw the thing work I thought that they had a blue diamond match hidden in the bottom of the piston..... nothing could work like that. I was wrong.

One of the team picked the thing up and showed me the parts. I wish I had gotten one of them to take home but I had other things on my mind at the time..... Oh well. Good luck!

A fire plow is basically the old boy scouts rub two sticks trick. A soft board, a v-shaped trench, and with a stick you rub up and down the trench. I've only done this a couple of times, with Barry Keagan and Mike Fairbanks. To do this alone, you have to be built like a Brick S-house and rub like a maniac. Very inefficient and very very hard to do.

A fire saw is much easier. You use a piece of split bamboo as a board, use shredded bamboo as tinder underneath, and saw another piece of split bamboo at a 90 degree angle to the first. Once you saw right through the bamboo, a coal forms on the under side. Steve Watts of the Schiele museum in NC showed me this technique.

That's the briefs, it would take a long time to explain it properly

here, maybe Ben has instructions already written down about this.

These are all things which can be learned at the great TRIBE gathering which Ben holds each year.

X-Mozilla-Status: 0001

Whether fire by friction is by bowdrill, handdrill, fire saw or fire thong, the theoretical principle of what makes this work is very useful to know. I will try to put words on something that anyone who has practised these skills for a long time tends to know by "feeling".

When wood is rubbed against wood, one of the materials is harder than the other. Even when the wood for fireboard and spindle are of the same wood, the spindle is harder than the fireboard in the sense that the fibers are cross grain rather than with the grain. Thus, basic theoretical principle #1, the harder wood grinds wood dust from the softer wood. Of course, some wood is ground from the harder of the two wood pieces too, but much more from the softer of the two, in this case the fireboard. Principle #2, is that when wood grinds hard enough, wood dust is created in the form of sawdust. Principle #3, when wood grinds hard enough and/or fast enough, heat is generated and the sawdust starts smoking and charring.

Now, the following is very important. Usually, sawdust is light, and when you rub wood, the sawdust moves away from the friction area and thus cools off, and new wood is rubbed which creates new sawdust which is cooler. This means that theoretically, you can do this forever and never obtain a coal or a fire.

Principle #4, then, is that to obtain a coal, YOU MUST RUB WOOD OVER AND OVER ON THE SAME SAWDUST. This is why you cut a notch in the fireboard, for instance. The hot sawdust gets wedged in the notch, preventing it from moving away from the friction area, and you are then rubbing over and over on the same sawdust and a coal will get created at that exact spot.

The coal then spreads to the remaining sawdust, making it grow, creating sufficient heat to flame tinder.

Principle #5, weight. Ususally it is not sufficient to have the burnt sawdust wedged in between a crack. There is also a weight consideration. The pile of sawdust must be big enough and therefore heavy enough to prevent the newly formed sawdust from moving it and cooling it off.

The 6th principle deals with the fact that for fire to occur, there must be sufficient combustible material. If there is not enough wood sawdust around the forming coal, it will not gather the momentum necessary to grow to usable size. Just like a fire can't be built with a match and a single stick, a coal cannot form if there isn't enough burnt sawdust around it.

Finally, 7th principle, a fire needs air to complete the heat-combustible material-oxygen trio necessary for ignition. This is much less important in practice because the small wood sawdust balls

under a microscope reveal plenty of air space between them.

Now we can look at practical questions. Can a bowdrill fire be made without a notch? Yes, it makes sense now, doesn't it? Just keep drilling long enough and hard enough so that the burnt wood sawdust pile around the friction area gets big and heavy enough not to move as you keep drilling. I have obtained up to 5 coals at once all around the drilling area this way.

What about the fire saw. Well, as the saw traverses the bamboo half round board, burnt wood dust accumulates underneath and you are rubbing back and forth on the same pile of wood dust which can't move because it's stuck underneath the board! As in bow drill and hand drill, it is now obvious (or should be) that filling the notch with tinder will prevent a coal from forming...

Fire thong works on exactly the same principle. The thong goes underneath a piece of wood which is split open about 1/4 inch, and burnt wood sawdust accumulates above the thong and gets wedged in that split and can't move. Once the crack is full, the thong rubs back and forth against the same wood powder and the coal ignites there.

The fireplow technique is harder to understand and doesn't work everytime because it relies on brute strength to generate sufficient heat in the pile of wood dust to ignite a coal at a random spot in the pile. Since this technique cannot be duplicated precisely the same way everytime, it is hard to come to a conclusion about what is happening but I think it is this. As the pile of wooddust at the bottom of the plow gets heavy enough and cannot move, the heat transfer from the friction area ignites a coal on the bottom edge of the pile, which usually manifests itself as a coal on top of the pile when it is accidentally hit by the grinding stick. Note that I have tried making artificial fireplows by tying sticks to my jigsaw blade and was not able to produce fire! The principles are not respected accurately in this technique, and probably a random crack between the dust pile and the plow board must permit the formation of the coal. Scratch me!

As for the new "fire hole" technique, there must be a crack in one of the pieces of wood in which burnt wood dust can accumulate. It will most probably look like an upside down fire saw. Can't get away from the principles if it is to work. Looking forward to Ben's post on this.

Hope this helps...

Eddie,

I first saw the fire plow demonstrated at the Polynesian Cultural Center in Hawaii...there are some awesome fire-making materials in the tropics.

Here in the states, Bart Blankenship is quite profecient with the fireplow; I watched him demonstrate it at Rabbitstick Rendezvous. In their book "Earthknack" (ISBN 0-87905-733-5) Bart and Robin say they use cottonwood and sotol (a desert plant similar to yucca or agave). I cannot tell if they are using those materials together or in independent sets.

Bart and Robin are wonderful people. For information on their school write to EarthKnack, Box 19693, Boulder, CO 80308. They host the EarthKnack Gathering in Colorado in June.

Always Peace,

Thomas J. Elpel

Subject: Fire Plow request

Content-Type: text

Status: U

X-Mozilla-Status: 0001

Anyone have any insights or information on the fire plow? I have heard of this, but have not seen any drawings, instructions etc. I have become proficient (read more successes than failures) at the bow drill, hand drill, fire saw etc. and would like to learn this technique.

thanks,  
eddie

> Anyone have any insights or information on the fire plow?

I learned the fire plow while in Hawaii. It was demonstrated at the Polynesian Cultural Center by a Samoan. The apparatus is one 4-6 foot long wrist thick pole that is flattened on two sides. This flattened portion is only about the last two feet of the pole. You sit kind of side saddle on the unflattened part of the pole with the flattened part extending out in front of you. (Although, it really helps to have the whole thing flat to learn it!) The plow is 12-18 inches long and about 3 inches wide. It is pointed at one end to about a 45 degree angle. Looks about like the top of a picket fence.

Fingers of both hands are interwoven and the plow is held point down against the fireboard. The thumbs are at the back of the plow. Start out slowly and smoothly with nice long strokes to work a groove in the fireboard. It will depend upon the wood and your skill as to how deep you want your groove. It is kind of like burning in the holes of a bow drill before you notch it.

Rest a second after you get the groove in. To produce the coal, it is like the bow drill: use nice long strokes, gradually increase pressure and speed. After about twenty or thirty fast strong strokes you should get a coal at the end of your groove if you selected good wood.

Be as relaxed as possible. Use your weight more than your muscles.  
Give it everything you have got those last fifteen strokes or so.

Have fun!

Hey everyone, here's something new and exciting. I just about had an orgasm when I read about this!

Thanks to Ben Pressley for bringing it to my attention. Folks, please try this one for me! (I can't because I broke my spine a couple of weeks ago playing hockey. I'm well on my way to full recovery now, there will be no permanent damage, the doc confirmed this yesterday, but I have to wait at least two more months without doing any strenuous activity whatsoever. Thanks to all who have shown concern...)

BEN PRESSLEY WROTE:

Andre, I'm just sending this to you, you can send it to the rest of the group, if you want. I noticed in your intro to the primitive skills group that you mentioned you had not found any firesaw material successful where you live. Try this, Barry Keegan and Mike Fairbanks came up with this one. Remember the New Guinea fire saw we played with at TRIBE Gathering with the bamboo strip and basswood hearth? Remember

you came up with the idea to elongate the strip by using two other attached bamboo sections for handles? Well, Mike Fairbanks was one of the guys there that successfully made an ember, well later on he came up with the idea of taking the split open, wedged open hearth, made from any soft, dry wood in hand...stuff it full of tinder, loosely...make a pinky sized impression in the tinder to receive the ember...take this hearth in hand and rub it up and down on a wedge of any hardwood jammed into the ground vigorously...and if you are good as Mike or Barry, you'll have an ember in 10 seconds lodged in the opening you made in the tinder bundle! I may have sent you a copy of Barry's drawing on this in the stuff I sent you, if not let me know. It will also be in the next TRIBE newsletter in March. Barry is ready to give up hand drill and bow drill for this method, he says it is so easy!

Benjamin Pressley  
benjamin@perigee.net

BEN, let's find a name for this technique! How about the fire hole?  
What does Barry Keagan or Mike Fairbanks call it?

Cheers,

Andr 

As far as I know they call it another fire saw technique. It is technically a fire saw, when you think about it.

Chris Smith wrote:

>Mention is also made of the fire plow and fire saw. If this isn't too far off-topic, what are those?

A fire plow is basically the old boy scouts rub two sticks trick. A soft board, a v-shaped trench, and with a stick you rub up and down the trench. I've only done this a couple of times, with Barry Keagan and Mike Fairbanks. To do this alone, you have to be built like a Brick S-house and rub like a maniac. Very inefficient and very very hard to do.

A fire saw is much easier. You use a piece of split bamboo as a board, use shredded bamboo as tinder underneath, and saw another piece of split bamboo at a 90 degree angle to the first. Once you saw right through the bamboo, a coal forms on the under side. Steve Watts of the Schiele museum in NC showed me this technique.

That's the briefs, it would take a long time to explain it properly here, maybe Ben has instructions already written down about this.

These are all things which can be learned at the great TRIBE gathering which Ben holds each year.

Whether fire by friction is by bowdrill, handdrill, fire saw or fire thong, the theoretical principle of what makes this work is very useful to know. I will try to put words on something that anyone who has practised these skills for a long time tends to know by "feeling".

When wood is rubbed against wood, one of the materials is harder than the other. Even when the wood for fireboard and spindle are of the same wood, the spindle is harder than the fireboard in the sense that the fibers are cross grain rather than with the grain. Thus, basic theoretical principle #1, the harder wood grinds wood dust from the softer wood. Of course, some wood is ground from the harder of the two wood pieces too, but much more from the softer of the two, in this case the fireboard. Principle #2, is that when wood grinds hard enough, wood dust is created in the form of sawdust. Principle #3, when wood grinds hard enough and/or fast enough, heat is generated and the sawdust starts smoking and charring.

Now, the following is very important. Usually, sawdust is light, and when you rub wood, the sawdust moves away from the friction area and

thus cools off, and new wood is rubbed which creates new sawdust which is cooler. This means that theoretically, you can do this forever and never obtain a coal or a fire.

Principle #4, then, is that to obtain a coal, YOU MUST RUB WOOD OVER AND OVER ON THE SAME SAWDUST. This is why you cut a notch in the fireboard, for instance. The hot sawdust gets wedged in the notch, preventing it from moving away from the friction area, and you are then rubbing over and over on the same sawdust and a coal will get created at that exact spot.

The coal then spreads to the remaining sawdust, making it grow, creating sufficient heat to flame tinder.

Principle #5, weight. Ususally it is not sufficient to have the burnt sawdust wedged in between a crack. There is also a weight consideration. The pile of sawdust must be big enough and therefore heavy enough to prevent the newly formed sawdust from moving it and cooling it off.

The 6th principle deals with the fact that for fire to occur, there must be sufficient combustible material. If there is not enough wood sawdust around the forming coal, it will not gather the momentum necessary to grow to usable size. Just like a fire can't be built with a match and a single stick, a coal cannot form if there isn't enough burnt sawdust around it.

Finally, 7th principle, a fire needs air to complete the heat-combustible material-oxygen trio necessary for ignition. This is much less important in practice because the small wood sawdust balls under a microscope reveal plenty of air space between them.

Now we can look at practical questions. Can a bowdrill fire be made without a notch? Yes, it makes sense now, doesn't it? Just keep drilling long enough and hard enough so that the burnt wood sawdust pile around the friction area gets big and heavy enough not to move as you keep drilling. I have obtained up to 5 coals at once all around the drilling area this way.

What about the fire saw. Well, as the saw traverses the bamboo half round board, burnt wood dust accumulates underneath and you are rubbing back and forth on the same pile of wood dust which can't move because it's stuck underneath the board! As in bow drill and hand drill, it is now obvious (or should be) that filling the notch with tinder will prevent a coal from forming...

Fire thong works on exactly the same principle. The thong goes underneath a piece of wood which is split open about 1/4 inch, and burnt wood sawdust accumulates above the thong and gets wedged in that split and can't move. Once the crack is full, the thong rubs back and forth against the same wood powder and the coal ignites there.

The fireplow technique is harder to understand and doesn't work everytime because it relies on brute strength to generate sufficient heat in the pile of wood dust to ignite a coal at a random spot in the pile. Since this technique cannot be duplicated precisely the same way everytime, it is hard to come to a conclusion about what is happening

but I think it is this. As the pile of wooddust at the bottom of the plow gets heavy enough and cannot move, the heat transfer from the friction area ignites a coal on the bottom edge of the pile, which usually manifests itself as a coal on top of the pile when it is accidentally hit by the grinding stick. Note that I have tried making artificial fireplows by tying sticks to my jigsaw blade and was not able to produce fire! The principles are not respected accurately in this technique, and probably a random crack between the dust pile and the plow board must permit the formation of the coal. Scratch me!

As for the new "fire hole" technique, there must be a crack in one of the pieces of wood in which burnt wood dust can accumulate. It will most probably look like an upside down fire saw. Can't get away from the principles if it is to work. Looking forward to Ben's post on this.

Hope this helps...

I just caught the tail end of this thread. I still am having a hard time visualizing the fire saw as described. Can some one take a stab (one more time) at explaining this to me, as I'd like to try it. A book reference would be good too. Or maybe one of the survival/computer guru's could build a gif file for our viewing pleasure.

No need to clutter list with this old thread. (If you dont think it will be of general interest, then just send to me)

Thanks  
Kelly Harlton

Well, Mr. Stormbringer, theoretically this description could not work because there is no way that the wood dust can accumulate and build up enough heat to create a coal. Please look at my next post on fire by friction theory and you will understand why. Ben will be posting more details on this actual technique later.

I am sorry for being so thick headed, but the "fire hole" idea caught my eye while I was catching up on my mail.

Is this an accurate summary:

You take stick A (a softwood) and hollow out a portion of it. Fill the hollowed out portion with tinder.

Then rub stick A against stick B (a hardwood). You rub the hollowed end with the tinder in it against stick B. Then the coal will fall into the tinner and you coax it into flame?

It seems, well, too easy.... Any clarification would be appreciated.

Thanks for your understanding and help.

I was speaking with Barry Keagan about this new technique yesterday. He gives 90% credit to our friend Mike Fairbanks on this one. Still trying to reach Mike...

He says he was successful with a tinder hole about the size of a small thimble, using a hickory upright and a basswood crosspiece with a crack of about 1/4 inch.

The theory of this makes sense: the friction fills up the thimble size hole surrounded by tinder with charred wood dust (which moves upward just as in the fire thong technique) and once the thimble is full, quick short strokes just over the hole make the crosspiece move back and forth over the same charred dust and a coal is created there.

Lots of elbow grease...

No. Here is how it is done. Take a soft, dead dry wood (Anything you can press a thumbnail into that is not resinous. i.e. basswood, willow, cottonwood, etc.). Split, but not all the way down, just enough to prop open with a rock or wooden wedge. Fill with loosely fitted tinder and poke a pinky-sized hole in the tinder. Drive another piece of wood, hardwood (hickory, oak, etc.) into the ground that is sharpened to a long edge and driven in the ground at an angle so you can hold it against your midsection. Rub the split and wedged piece vigorously over the edge of the hardwood. In about 10 seconds you will have an ember lodged in the split. You can tell when you have one for it will continue to smoke when you stop. Let it sit and build in size and become more solid. Then transfer it to a more substantial tinder bundle and blow into a flame.

If you would like a drawing that explains it real well, just write my snail mail below and send me \$2 to cover copy and shipping costs.

> Ben, have you tried this yourself yet?

Yes. It is a new technique, that I was only recently introduced to. My explanation was a combination of Barry Keegan's experience and mine. He has tried it and been more successful consistently than me. He is the 10 second man. It has taken me a little longer, when I have been successful. Maybe his 10 second time did not include slow moving long strokes for pre-heating before really pressuring down. I hope I didn't mislead, like I've mastered it or something. I am speaking excitedly

about this technique because I see its potential in the times I have had success with it. It is as easy as the Bamboo and more versatile, because of the variety of materials you can use. I think you will probably have no problem with it. I'm still working on mastering this one. Fire Saws wear me out!

> Please include precise dimensions if you can of the width of the crack  
> where the rubbing takes place, the width and depth of the pinky size  
> hole, the tinder used, and especially the width of the ridge on the  
> bottom piece. Wish I could try this!!!

H-mm. Precise dimensions. I don't really have any precise dimensions to offer you. I have had success with Black Willow, mostly. Cottonwood shows promise. For some reason I can't get an ember with this technique using yucca.

The opening where the ember forms, where your applying friction, can be 1/8 to 1/4 inch. Tinder should be placed very loosely sort of forming a tiny bird nest (maybe this acts like the notch in bow & drill and allows a build up of heat as well as containing the ember?). You can poke this out with a stick to form this pocket. I have used dry hornet nest for tinder.

As far as diameter of hand held hearth. I don't think its that important. I've used 3/4 inch to 1-1/2 inch diameter.

Th width of the ridge of the bottom piece is like a knife edge, sharp.

> I wish we could get Barry Keagan on this list, and John McPherson, and  
> Steve Watts, and etc... I've been working on George Hedgepeth, he  
> should be getting his computer soon. Can you work on some of the others?  
>

Barry hasn't got a computer. I'm trying to get him to get one. John McPherson has a homepage but he may have got someone to do this for him for advertising. I'll have to ask him. I have asked Steve Watts. He just says he never would get anything done if he connected to the Internet. And, George, it's just a matter of time. He is headed in that direction.

John McPherson did send me a copy of his new book, though. Excellent! He is a super guy. He also mailed TRIBE a \$50 donation.

I received a very important post in french from Pascal Chauvaux of France who is a member of our group. For those who don't read french, I have translated the essential at the end of this:

>AndrÈ,

Merci de m'avoir indiquÈ le PRIMITIVE-SKILLS-GROUP !

J'ai rencontrÈ quelques difficultÈs pour m'abonner, mais tout est bien maintenant.

J'ai reÁu d'Èjý plus de 80 messages, et cela semble bien intÈressant.

Un des domaines qui m'attire le plus est la production de feu. Nous avons, avec quelques amis d'une

association archÈologique de la rÈgion de LiÈge en Belgique, beaucoup travaillÈ la production

(prÈhistorique) du feu. Si cela t'intÈresse, je peux t'envoyer la copie d'un article que nous avons

publiÈ (en FranÁais) :

L'obtention du feu par percussion : approche expÈrimentale et tracÈologique, in Bulletin des

Chercheurs de la Wallonie, Tome XXXI, 1991, 19-49.

On y parle notamment des initiateurs (champignons) testés.

J'ai de bons contacts avec des archéologues suisses, et j'ai reçu un article indiquant les champignons utilisés (une quinzaine) par les Néolithiques du lac de Neufchâtel en Suisse. Quelques-uns étaient des initiateurs pour le feu.

En ce qui concerne le feu par friction et percussion, je connais un bon spécialiste français : Jacques Collina-Girard. Il a publié quelques articles intéressants, et je peux t'en faire parvenir une copie si cela t'intéresse.

Nous nous sommes spécialisés dans les briquets en fer, et j'en ai d'ailleurs forgé une quarantaine la semaine dernière. Il faut dire que nous avons fait des recherches récemment, et que la plus vieille occurrence d'un briquet en fer remonte à 400 BC. Il s'agit de 3 briquets en fer provenant d'une sépulture collective de l'âge du fer (La tène), dans la grotte Ambre, à Eprave en Belgique. Ils ont une forme très différente des briquets en fer connus. J'en ai quelques copies, et si tu es intéressé, je peux t'en faire parvenir un (avec les dessins des pièces originales). Je voudrais d'ailleurs le faire savoir au PRIMITIVE-SKILLS-GROUP. Peux-tu leur transmettre un message leur proposant gracieusement un briquet en fer. Je m'engage à envoyer gratuitement un briquet et quelques explications à ceux qui m'en feront la demande.

Comme chaque année, le premier jour de l'an, je vais me promener au Cap Blanc Nez, au bord de la mer entre la France et l'Angleterre, où ils ont creusé le tunnel sous la manche. On y trouve du silex dans la craie, mais aussi énormément de marcassite, le fameux bisulfure de fer qui est attesté comme le plus ancien procédé de production de feu (tant que l'on ne retrouve pas une drille en bois). J'ai toutes les références des sites où on a retrouvé de la marcassite (paléo supérieur). Je peux également t'envoyer un kit complet : marcassite, briquet en silex, amadou.

Voilà, j'espère que si des renseignements que je te fournirai sont intéressants, tu auras le courage d'en faire une traduction sommaire pour le faire savoir aux membres du PRIMITIVE-SKILLS-GROUP. Mon anglais n'est pas assez bon pour le faire moi-même.

Merci pour ton obligeance.

Meilleurs vœux de santé et de prospérité à l'occasion de l'année nouvelle, à toi et aux membres de ta famille.

Pascal Chauvaux

Pascal.Chauvaux@gate71.be

Ok, here's the gist of the post:

Pascal and others in France in archeological circles have worked severely hard for a long time on flint & steel tinder. They found references to 15 types of fungi which were used for flint & steel tinder and tested them. He has offered to send me scientific articles on all of these experiments conducted in Europe and Switzerland especially, but they are in french.

His group has specialized in making striking bats based on a very old one they discovered which is dated 400 BC. These bats are apparently quite different from the ones we know about.

Pascal has offered to send a replica and drawings of the original to those of the group who want one free of charge! (I'm not sure that he will be able to do this when he finds out how many of us will be interested!)

He says that in the undersea tunnel which was dug years ago between England and France, that they have discovered Marcassite and other evidence of primitive fire making ways.

Wow, thanks for such a great post, Pascal, and in the name of the group, thanks for such a generous offer.

Please, everyone, send your requests directly to Pascal by private E-mail, not to the group.

I have found that the dried top of the cattail that has been broken up and fluffed up will catch a spark from flint and steel very easily. In fact, if you do not watch out, the explosion of the initial flame will burn your hands before you can get out of the way.

Ok Jim, you had me fooled there for a while! What you are referring to is a commercial flint striker which is made of magnesium with a striking insert made of (what's the name I'm searching for?) ium. This magnesium match puts off a very very hot spark that will make just about any kind of good tinder flame up.

However, when we talk about flint and steel here, we are talking of natural flint pieces struck with a piece of steel. I don't know of anyone who has found any natural tinder fine enough to catch that kind of spark other than the fungus Inonotus obliquus. That's why I was so surprised by the cattail story.

Just goes to show how simple details can mislead one's thinking and get some authors writing down things which do not work.

Thanks for helping us clear this up.

I was using a simple flint striker that fit into the side of a knife handle that I had ordered from the Sportsmans Guide Magazine. I just raked the knife blade along the length of the flint piece (about 2.5in. long X 1/8in wide), and got a large swoosh of sparks that when done close to the little pile of cattail fluff, resulted in an explosion of flame. The fluff burns out rather quickly, but with some dry leaves or other tinder next to it, results in a nice warm camp fire.

Howdy!

First, thank you so much for your generous and kind appraisal of my fire piston article. It was a lot of work but very fun.

I am glad that you brought up the question of the shredded bark tinder that was mentioned in the article. I was reporting what John Rowlands said he used but in all my years of experimentation on the subject of catching sparks I have never had any succes with the dry, finely shredded bark. In addition, no one who is into primitive tech. that I have talked to has indicated success either. Ditto for mouse or birdnests. I have only had success with charred material. The only thing I have seen that is uncharred that will catch and nurture a spark is a type of fungus that is sometimes found in birches or cherry trees and it is amazing to see.

Because of your question I am going to edit my article to indicate the above observations. I appreciate you input and look forward to further conversations as well. It sure would be fun to make a living writing things like that firepiston article.

Happy Holidays, Andre

I have been communicating with Wyatt Earl who wrote the article on fire piston and was asking him about tinder other than charred cloth. Our communications might interest some of you... here goes.

Howdy AndrÈ!

First, thank you so much for your generous and kind appraisal of my fire piston article. It was a lot of work but very fun.

I am glad that you brought up the question of the shredded bark tinder that was mentioned in the article. I was reporting what John Rowlands said he used but in all my years of experimentation on the subject of catching sparks I have never had any succes with the dry, finely shredded bark. In addition, no one who is into primitive tech. that I have talked to has indicated success either. Ditto for mouse or birdnests. I have only had success with charred material. The only thing I have seen that is uncharred that will catch and nurture a spark is a type of fungus that is sometimes found in birches or cherry trees and it is amazing to see.

Because of your question I am going to edit my article to indicate the above observations. I appreciate you input and look forward to further conversations as well. It sure would be fun to make a living writing things like that firepiston article.

Happy Holidays, Andre

Hi Wyatt,

You might like to know that I have finally identified that birch fungus you are talking about. It is sometimes called Chatoquin or Bearshit but the scientific name is *Innonotus obliquus*. It is indeed a fungus (at first I thought it was a disease) but it is a white rot fungus rather than a brown rot like most rots we usually see. This white rot attacks the wood lignum and cellulose differently than brown rot and is responsible for forming a material which is similar in many ways to charred cloth. I am still looking into this and trying to find other fungi or material botanically related to *Innonotus* to try them out. Maybe this will help you with the tinder issue and maybe you and others can help pursue this research further.

*Innonotus* was also used medicinally in Russia, one source mentioned that (can't remember off hand, but I did write it down somewhere).

For tinder, this stuff is indeed amazing. One very fine spark into it and you can't put it out! However, I've noticed that if it dries out too dry, it no longer works. Much testing still to be done...

Best regards,

Andr 

PS We've got a great primitive skills group with many very knowledgeable leaders, you are very invited to join us!

I think you may be referring to Tinder Fungus. It's now a permanent fixture in my camping sack (along with Birch Bark) because it work so well.

Regards

For fire piston, "mountain" Mel Deweese is the only expert I know and he says he has only had success with tinder derived from a certain palm. I know that's a vague reference, I'll try to find out the exact name of the palm. In the meantime anyone who wishes to contact Mel, can contact him at: Nature Knowledge, 1825 Linden St., Grand Junction, CO 81503, Phone: 970-242-8507.

As far as flint & steel, I have only had success with charred material and an uncharred fungus from up in Canada that a friend of mine brought me at TRIBE Gathering. Amazing stuff. A small sliver catches a spark and it glows and glows. Maybe Andre remembers the name of the fungus I'm talking about. George Hedgepeth brought it with him that year you came to TRIBE Gathering.

Innotus obliquus is a common fungus and there is a great deal of information published about it. You can find some in forest pathology books and some in books on systematics of polypores.

I am surprised that it catches a spark so well. It is not the fungus known as "tinder fungus," which is Fomes fomentarius.

Innotus obliquus:

The imperfect form of the fungus occurs parasitically on trunks usually of *Betula* (birch) more rarely on *Alnus* (alder) and other hardwoods. The fruiting bodies of the imperfect form are conspicuous in that they are black lumps which are always found on the trunk 1-4 m above the ground. Only after the tree dies does the perfect stage develop under the bark and is often overlooked. Fruiting is annual throughout the year, found in Europe, North America and Asia.

Your letter to Mary Palm was forward to me. *Inonotus obliquus* was used frequently as a tinder and there are a number of "mushroom" identification books with information. Do you want references? There are also several other fungi that were used for tinder and appear to be superior to *I. obliquus*. *Fomes fomentarius* has been used in Europe as well as the US and Canada - and used by Native Americans. In the pacific northwest, Native Americans used other fungi such as *Phaeolus schweinitzii*. Let me know what kind of information you need.

Sincerely,

Robert A. Blanchette

Wow Tim, what a terrific post! First time I've ever heard of bird down  
being used as tinder. Quick, someone in the south run out and try this!  
No birds here right now, but maybe I'll sacrifice my old down jacket!

I'd appreciate anyone who knows more about this to please speak up...

Thanks, this is exciting!

>He uses the spongy, brown part of the "true Tinder Fungus

Mark, I'd like the scientific name. Andre has posted a name or two, and I'm waiting to hear from a friend whether I can find them around here. The polypores I'm familiar with are pretty tough customers and won't just crumble in your hands; so do you just cut 'em up and mash 'em with rocks until you get a powder, or what?

This is a new one for me also. It sort of boggles the mind to imagine running around in the woods looking for said bird down, but I have no doubt it was used in special instances for ceremonies etc.

My experience with flint and steel is limited personally, however I have a Native friend in this area who lights all his ceremonial fires using flint and steel (although he is very secretive about his materials. I get the sense in talking to him that he uses some kind of flint/iron pyrite combo. I will hopefully have an opportunity to talk to him more about the details in the future and you can be sure I will post what I can here at that time). What I am sure about is what he uses for tinder and I have since found references to the same material in books by Mors Kochanski and others. He uses the spongy, brown part of the "true Tinder Fungus which is the strange looking growths on the sides of live birch trees. He has been very firm in his insistance that it needs to come from a live birch tree. The fungus looks kind of like a "burned growth" and differs significantly from false tinder fungus which has a more uniform and shelf like appearance. If anyone is interested I can get

scientific names etc. and more information on these fungi.

Bird down, huh? :-)

Actually John I've been looking books trying to find the scientific

name for these things and haven't had any luck yet. Maybe someone else out there can help. Have you tried the fungus I call "true tinder fungus" yet to see if it will crumble? (it is a very strange looking glob on the side of live birch). I know the "false tinder" fungus is not easy at all to crumble. It sort of has the consistency of dry hardwood. Maybe that's why it needs to be soaked in lye first. Any other folks tried this?

Mark

I think that the reference to eagle down in the original quote may have been somewhat misleading. The source that was cited from was from the 1600s and the down may have been romanticised a little -- or perhaps they were using the good stuff for a guest. The Montagnais and Beothuk were coastal groups. They spent much of the year on the coast fishing, sealing, collecting shellfish, and raiding bird islands for birds, eggs, and down. Fluffy down from water fowl, such as the eider duck could be found in abundance, at the right time of year, at migratory bird colonies. I suppose that if eagle down burns they would have used it when available, but I think for the most part they would have relied on down from these nesting colonies.

cheers,  
Tim

I haven't experimented extensively with bird down, but the times I have tried I used Turkey and (don't tell anyone) snowy white egret (I didn't kill it, some animal did). They just melted. They didn't catch up flame. I'd be interested if anyone has had success with this, too.

The article submitted by Dr. Bourbeau was top notch. I was wondering if anyone has tried using charred pith as a coal enhancer tinder. I have had good luck using the charred center pith of mullein in demonstrations with flint and steel. The actual charring process is a little more tricky than it is when dealing with cotton, but it seems to work nonetheless. Any thoughts?

I have also charred and used the pith of mullein as well as red sumac. They do char and work very well. They are also difficult to keep together in a pile. I usually make a birdnest of fluffy tinder and poke a finger sized hole to hold it as tightly together as possible and it works very well.

And I also add my praise for Andre's excellent article on ember enhancers. This is the kind of posts I like to see.

I would like to hear some discussion from the group from anyone with experience on what, if any, ember enhancers you use. By ember enhancer I mean, is there anything you have found successful that helps to increase the size of your ember that you transfer an ember to (usually produced by friction methods) prior to transferring it to a tinder bundle?

Some people, for example, will actually place cattail fluff beneath the notch and between the fireboard and ember transfer plate for the purpose of 'holding' an ember and allowing it to grow a little bigger. I, for one, do not like cattail fluff. I have had too many embers smother out doing this. One ember enhancer I like is rotten, corky, punky wood. It will not catch up into flame, but given time that piece of rotten wood will become one big, glowing ember.

Benjamin

The best way I have found to enhance an ember was to leave it in the notch for 1.5-2 minutes occasionally waving my hand over the ember. After 2 minutes the ember will have grown larger and more stable and then using a knife, I carefully sererate the ember from the notch and place the ember in the tinder. In my experience this has been the best method.

Yes, that is essential even with ember enhancers. I started this thread to see what if any additional things anyone does to help assure the growth of an ember, a little extra insurance, if you would. I hope this clarifies my query. I'm just curious what other people use.

Yes, I've did that, too. I think it is also important to wait and let  
the ember grow and fuse together more solid. My query, though, is out of  
curiosity if anyone uses anything extra to enhance the size of the  
ember, once it is produced. Some people use cattail fluff, some rotten  
punky wood, as I mentioned.

A burl is part of the tree or shrub. I don't remember my botany all that well, but I think burl is all meristematic tissue, which means you can grow a new tree from it. A lot of woody plants that grow in areas of frequent fires sport underground burls that allow them to rise like the proverbial phoenix after a blaze. A "conk" is just a common name for any big ole polypore fungus stuck to the side of a tree. It's a lot harder than your average mushroom, but it's still a fungus.

Lurker from Alberta

Hey great list gang! Ive made numeous fires from both the tinder fungus and th false tinder fungus mentioned in Mors Kochanski's book

You may have fun finding scientific name for the "true tinder fungus" as I not yet convinced that its a fungus at all. I believe it is more like a "burel" or "Conk" (sp?) not unlike you would find on an aspen. The consistancy from the inner portion looks, feel, and crumbles exactly the way that cork does. Its great stuff and has many uses. for firestarting it makes a great long lasting ember. The false tinder fungus if pressed I could dig up the scientific name no prob. I definitely will not crumble, in fact you have to slice thin pieces off the layer found just under the outer shell, and then process by boiling in a hard wood ash slurry, and drying. Both these work well with sparks from my axehead or knife.

Retgarding thread on carrying an ember, The only thing I've tried is "Punky wood from a stump" . I had read(cant remember where) that some Indians use to spit a piece of punky wood, sandwich the ember in the middle (making sure it starts to smolder) and then wrap in a peice of leather and tie so you and carry it on your peson. What I found is this worked OK but was subject to moisture content in wood. (that is, if the woods too wet, the ember will extinguish, and if the woods too dry, the ember grows too quickly, and it becomes too hot to handle)

Hope this information is of some value

Kelly

Actually John I've been looking books trying to find the scientific name for these things and haven't had any luck yet. Maybe someone else out there can help. Have you tried the fungus I call "true tinder fungus" yet to see if it will crumble? (it is a very strange looking glob on the side of live birch). I know the "false tinder" fungus is not easy at all to crumble. It sort of has the consistency of dry hardwood. Maybe that's why it needs to be soaked in lye first. Any other folks tried this?

Mark

Hi folks,

Pascal Chauvaux of Belgium just sent me a message in French which might interest you. In essence it translates as follows:

For flint & steel fire, cattail fluff does not work. However, you can "improve it" by washing it in a solution of 5 parts warm water to 1 part of potassium nitrate. After drying, it will now work.

Question for all you chemists: what's potassium nitrate, and is it possible to manufacture it or find it in the wilderness somehow?

Thanks to Pascal for sharing this.

Hi Ya'all

I'll try to give you a place to look on this one.

>However, you can "improve it" by washing it in a solution of 5 parts warm water to 1 part of potassium nitrate. After drying, it will now work.

>

>Question for all you chemists: what's potassium nitrate, and is it  
>possible to manufacture it or find it in the wilderness somehow?

During my military training we were taught how to make explosives with common chemicals and in some cases, how to make the chemicals themselves.

Potassium Nitrate is also known as "saltpeter (Saltpetre)" and is the oxidizing agent in black powder.

It is formed ..... or precipitated from..... feces. Turds lying in a field will, after some time, develop a whitish crystalline powder which is part uric acid and part potassium nitrate. This substance, the crystals, not the turds, are collected and washed to separate the chemicals. I will try to remember the exact process we used and post that later. I do remember that the crystals with the highest concentration of Potassium nitrate were found on the underside of the turd, next to the ground.

This powder was mixed in the classic proportions with either charcoal and sulphur, or charcoal and sugar, to make a stinky explosive. The sugar mix smelled like a candied turd. Do NOT try this in your rifle! It is OK in Bamboo nail guns.

I'll look in my notes for more info on the process. It is simple and the saltpeter is useful in a number of ways to enhance ignition etc. It is not effective in curbing sexual drive as some legends will have us believe.

Hello,

Potassium nitrate is a chemical compound, KNO<sub>3</sub>, which is produced by nitrification in soils used in gunpowers, fertilizers and preservatives (i.e., saltpeter). I would imagine that a good knowledge of your local natural resources would point you to a geologic source otherwise I'm not sure how one might manufacture it.

A short intro. I am a project archaeologist involved with cultural resource management studies on Iowa Department of Transportation projects. Besides my interest in arhcaeology and my degrees in Anthropology I have been interested in primitive skills since I was quite young. I grew up in the Duluth, Minnesota area and have had extensive outdoor time throughout northeast and northcentral Minn., northern Wisconsin and the U.P. of Michigan, and central Ontario. Since leaving Minn. for other points I have lived in Oregon, South Dakota, and Indiana prior to moving to Iowa. I have tried to practice the skill I already knew and learn as many new ones as I came across. I am a flintknapper of some 10 years and am branching out into other experimental areas of prehistoric technology, it all helps me understand and analize better the real archaeological stuff. This listserv is wonderful and I am glad to be a part. I'll contirbute as I can and look forward to learning Lots of new stuff about living in the natural world.

To share a quick story....I was doing a flintknapping demonstration at the University of Northern Iowa one afternoon and had checked in with the director of the student union, who was the organizer of the Multicultural Week of which I was a participant. On walking outside to where I was to

knap, the director said to me...."So, when the powers goes off for good, our computers all fail, and all of our industrial machinery grinds to a halt, we should come and find you if we want to continue to eat and such, right?" Needless to say I chuckled, agreed with her, and said that fortunately all can learn to knap and survive if the desire and (perhaps more so) the need were there. Thanks for the list Dr. Bourbeau! Mark.

Sure, It can be "manufactured" . The best source is a bat cave that's  
been used for a while. Potassium nitrate is one of the salts that's  
expelled from the bodies of mammals, I think in urine, but it could be  
both. Bat Guano, used to be mined for this. Chicken poop should be good  
too and if you're close to an old outhouse, human waste is high in nitrates  
(potassium nitrate) too. If it's poop and good fertilizer, then it's  
probably a good source of potassium nitrate.  
The best stuff is the well aged stuff. In bat caves, it's the stuff that  
looks like dirt, not the fresh.

BTW, potassium nitrate is also known as nitre. (That's right, it grows on  
the walls of catacombs).

Now, to get the stuff out... It's a leaching and drying process like  
extracting lye from ashes. Water is poured through a pile of ... (be nice  
merv!) preprocessed potassium nitrate ore, the liquid coming through it is  
captured and dried in the sun. The resulting crystals are pretty pure  
potassium nitrate.

The easiest way, if you have the materials is to build a hopper to hold the  
ore and a catchment below it for the liquid that comes through.

Any hydro-carbon soaked in potassium nitrate solution and dried should make a  
good tinder. Now if we only had some sulfur and some charcoal, we'd be on  
our way to fun stuff! This combination should make good tinder too!

Sticking his foot in it again...

Merv

I'm not a chemist but I may have part of the answer. Potassium Nitrate aka salt peter was used by Mt. Men in making black powder. The chemical can be found where animal urine has evaporated (Around barnyards or outhouses). White crystals form which are collected and ground into a powder. Add equal amounts of powdered sulphur and charcoal and you have basic black powder. I have collected and processed the ingredients but have not made any powder.

How about the concentrated urine dropped/squirted by owls  
and hawks? Would that stuff be better?

Cool! As far as Potassium Nitrate, it is one of the key elements in gun powder. Gunpowder= Potassium Nitrate+Sulfur+Charcoal. It is also known as saltpeter. I do not think it is that abundant in the wild. I know it is mined out of caves. If I'm not mistaken water was ran through it in the U.S. Civil War and the run-off was nitro glycerin. You can buy it at a drug store, though.

That's what it was! I knew it came out of a cave. It isn't mined it comes from bat guano. Duh! I remember hearing that on a tour of the Lost

Sea cave in Sweetwater, TN. There was a potassium nitrate operation going on there during the Civil War.

Making nitro is considerably more complex than running water through potassium nitrate. I can supply the instructions if there are any real pyro maniacs out there.

Subject: Inonotus and other fungus as tinder

Content-Transfer-Encoding: 7bit

Content-Type: text/plain; charset=us-ascii

Status: U

X-Mozilla-Status: 0001

Hi everyone, I am forwarding this letter I received about tinders from professor Robert Paquette of Minnesota.

Dear Dr. Bourbeau,

An interesting book that discusses tinder from fungi is "Northern Bushcraft" by Mors Kochanski, published by Lone Pine Publishing. If you take the basidiocarps of *Fomes fomentarius* and pick apart the very top fibrous material, dry it and pull apart the fibers it will light with one spark very easily. This fibrous fungal mycelium seems to catch the spark easily and will then smoulder for some time. Its only this very top portion of the fruiting body that works. The *Inonotus* also burns well. There are references about its use for tinder but I do not think I have seen information on its chemical properties.

There is another fungus used by the plains indians, used as a smudge. Once this is lighted it will continue to burn completely for a long time - the same is true for large puff balls. It may be the fine fibrous characteristics of the mycelium allow it to burn so well. In the pacific northwest, *Inonotus* and *Fomes fomentarius* are not common and this other fungus, *Phaeolus*, was used. It probably has the same texture as cotton when dried and after the mycelium is pulled apart.

I will check some of my references and send you those that may apply to answer your questions.

Best regards,  
Bob Blanchette

Dear Dr. Bourbeau

Here's a list of references I pulled off the net ... you probably have them already. I have the new "Checklist of Canadian Mosses" list somewhere (might have some new Canadian info) but I lent it to one of our editors and can't lay my hands on it just now.

We have an expert mycologist in the office here (who worked on the above list). I'll check with him on Monday to see if he has any obscure or recent references that might interest you. I'll poke around myself as well.

Best,

Ken Farr

Tu as Écrit :

>Peux-tu d'Écrire davantage le processus de lavage. Comment fais-tu pour  
>empÍcher que le tout s'envole au vent?  
>

AndrÈ-FranÁois,

C'est simple, tu prÈpare la solution aqueuse (5 parts d'eau pour 1 part de nitrate de potassium) dans une petite poterie remplie ý moitiÈ. Pas de problÈme, le nitrate est la substance chimique la plus soluble dans l'eau ! A ce moment, juste au-dessus du pot, tu Ècrases avec les doigts la tÍte du roseaux o~ se trouvent les graines et tu recueilles ainsi des milliers de graines avec leur aigrette (qui facilite la dissÈmination par le vent). Tu en perdras quelques dizaines, mais il en restera toujours des milliers. A ce stade, il est impossible de les enfoncer dans la solution aqueuse : les aigrettes sont hydro-rÈpulsives ! Il faut mettre la poterie ý chauffer sur le bord d'un feu de bois. Avant l'Èbullition de la solution, il sera facile d'enfin enfoncer les graines de roseaux dans la solution avec une petite branche.

Je veux te rassurer : le nitrate de potassium entre dans la composition de la poudre noire, mais il restera inoffensif tant qu'il sera dans une solution aqueuse !

Quand le mÈlange ý refroidi, on prend une poignÈe de "fibres brunes" et on l'essore en l'Ècrasant dans la paume de la main. Les graines de roseaux sÈcheront facilement ý l'air, car elles sont plus compactes maintenant. Le bain chaud ý enlevÈ (dissous) la substance qui faisait que l'aigrette Ètait hydro-rÈpulsive (cqfd).

c'est intÈressant d'apprendre que le nitrate de potassium se trouve naturellement dans les matiÈres fÈcales ! Je suis impatient d'en apprendre plus ý ce sujet.

NB : quand je ne trouve pas de nitrate de potassium, j'utilise du nitrate de sodium (mÍme rÈsultat).

Salut.

Pascal Chauvaux

The names of the birch tinder fungus you are referring to is Inonotus

obliquus. It can grow on live trees, but also on trees which have been dead up to 7 years. I am currently researching this subject intensively and will post something soon. The other fungus is called Fomes fomentarius, but needs preparation before using to get it to work.

As soon as the archives are ready, you will be able to read the Inonotus thread which has been thus far discussed.

Regards,

Andr 

Hi Ben and other ember enhancer enthusiasts,

Here's my 4 cents worth on this very important subject. Ben, as  
promised, this is another article for your newsletter on fire which you  
can copy and use.

Andr 

#### TINDERS AND COAL ENHANCERS

In a survival situation, fire can mean the difference between life and  
death. Warmth, smoke against insects, removal of psychological fear,  
purified water or melted snow, cooked food, building tools, etc., all of  
these fundamental concerns can be adressed by the survivalist through  
the use of fire.

There are many ways of obtaining primitive fire: by friction (bow and  
drill, hand drill, pump drill, fire saw, fire thong, fire hole) by  
compression (fire piston), by flint & steel, and by the use of the sun  
(magnifying lenses of ice and maybe even animal bladders).

All of these methods produce only a very small coal to start a fire  
with, and often obtaining that initial minuscule coal is only half of  
getting the job done. Without appropriate tinders to transform that  
small coal to a flame, there will be no fire. That is why knowledge of  
tinders is so very essential!

Tinder can be classified into 4 categories:

1. Coal enhancer tinders (make a coal grow into a bigger coal)
2. Coal-to-flame tinders (make a coal become a flame)
3. Combination coal enhancer and coal-to-flame tinders (both of above)
4. Flame-to-flame tinders (quickly make small flame grow to big flame)

1. Coal enhancer tinders are materials into which you put a very small  
ember to make that ember grow in size.

For example, if you take a 2 inch square piece of the fungus *Inonotus obliquus*, and place a small ember on it, the ember will transfer to the fungus, and after blowing a little, you will have a 2 inch square ember. A better known coal enhancer tinder is charred cotton cloth.

Obviously, tinder enhancers are very important, because they give you the possibility, from a very small fire-by-friction or fire-by-flint-and-steel coal, to produce a much bigger coal, which can generate sufficient heat to light up less-than-perfect tinder, such as wet birchbark or fine damp twigs. (In ideal situations, a bigger coal might not be necessary, a standard size coal from a bow drill fire being sufficient to light finely shredded dry birchbark, grass or other easily inflammable tinders.) But when it's soaking wet out, or -30 degrees, or when your bow drill equipment is poor and the initial pile of dust is small, you need coal enhancers. Coal enhancers are also absolutely necessary when starting a fire with a magnifying glass, especially when it is made of poor materials, such as ice.

2. Coal-to-flame tinders are materials you can use to make the coal blow up into a flame. A common coal-to-flame tinder is shredded birchbark. When you put a coal into a pile of coal-to-flame tinder and blow, the heat from the coal is sufficient to raise the flammable gas in this type of tinder to ignition levels. Many coal enhancer tinders, such as fungus, do not flame up, and you need to use a coal-to-flame tinder for this purpose.

3. Combination coal enhancer and coal-to-flame tinders are very special in that they can act either as a coal enhancer tinder and as a coal-to-flame tinder. A good example of this is scraped and shredded outside bark from cedar trees (*Thuja* spp.). When you drop a coal in a nest of this type of tinder, you can make your small coal grow, and with enough blowing, transform that large coal into a flame without having to resort to anything else.

4. Flame-to-flame tinders are those which need a heat source hotter than a coal can provide to flame up, but which give up an immense amount of heat very quickly once lit. All coal-to-flame tinders are also flame-to-flame tinders, but the reverse is not true. For example, set a match to a mature milkweed (*Asclepias* spp.) pod. There is nothing primer than this, the stuff almost explodes into flame. However, sparks or small coals will not ignite milkweed pods. Flame-to-flame tinders are usually found in abundance and will be useful once the initial flame has been produced.

Now for the actual down-to-earth materials:

#### 1. Coal enhancer tinders

The best coal enhancer is charred wood dust! You already know this, because when a fire-by-friction coal forms, you can watch it grow to the same size as your charred wood dust pile. Therefore, if you drill a couple of extra holes without a notch with long smooth strokes (without tiring yourself) and keep that dust, you can then add it to the dust in the notch after the coal forms to make the coal bigger. Obviously, you are not going to bother making a bow and drill set to get the wood dust needed for starting a fire with other means. In that case, you can use

a simpler approach to get the dust, for instance by rubbing a stick in a V shaped trench cut into another stick (as in the fire plow fire-starting method).

There are, of course, easier ways to obtain ember enhancers, and that is to use natural ones found throughout nature.

Here in the northeast, here are some examples of the better ones:

- 1.1 Charred wood dust
- 1.2 Inonotus spp. fungus
- 1.3 Fomes spp. fungus
- 1.4 Ganoderma spp. fungus
- 1.5 Polyporus spp. fungus
- 1.6 Poplar (populus spp.) inner bark, shredded
- 1.7 Cedar (Thuja spp.) outer bark, scraped
- 1.8 Juniper (Juniperus spp.) outer bark, scraped
- 1.9 Cattail (Typha spp.) heads, must be unfluffed!
- 1.10 Fireweed (Epilobium spp.) down
- 1.11 Goldenrod (Solidago spp.) down
- 1.12 Asteraceae family, down from many species
- 1.13 Charcoal from a previous fire
- 1.14 Some rotten woods, must have dried out first
- 1.15 Soft wood scraped with sharp blade

Of all of these, only a few will actually work in rainy weather. Forget about all the plants, they will be soaking wet. The mushrooms won't be dry enough, and the charcoal and rotten woods will be drenched. If you're lucky, you can find some dry tree barks, even in rain, under some very dense conifers and under overturned trees. If you're not lucky, that limits you to a single lonely source, but one which always, always works, no matter what, and that is wood scraped with a sharp blade. In the worst forest conditions which nature has to offer, there is always dry wood inside an arm sized piece. By splitting and/or breaking and/or wedging it open, there is the coal enhancer tinder for you to take. But not without the effort of scraping, plus all preliminary shelter building etc.

## 2. Coal-to-flame tinders

Here are the most common coal-to-flame tinders in the north-east:

- 2.1 Charred wood dust, lots of it
- 2.2 Poplar (Populus spp.) inner bark, shredded
- 2.3 Cedar (Thuja spp.) outer bark, scraped
- 2.4 Juniper (Juniperus spp.) outer bark, scraped
- 2.5 Fireweed (Epilobium spp.) down
- 2.6 Goldenrod (Solidago spp.) down
- 2.7 Thistle (Cirsium spp.) down
- 2.8 Soft wood scraped with sharp blade
- 2.9 Shredded birch (Betula spp.) bark

Of these, thistle down is by far the best! It is so incredible a material that it is the only source found thus far which will permit lighting a fire from the sparks of an empty Bic lighter.

Birch bark is also an incredible material in this category. When

everything else is soaking, the inner layers of the birch bark will be perfectly dry and useable.

In very wet weather, other than birch bark, only scraped wood will work.

### 3. Combination coal enhancer and coal-to-flame tinders.

Materials in this category are more limited. In the northeast, here are the main ones found thus far:

- 3.1 Charred wood dust, lots of it
- 3.2 Poplar (*Populus* spp.) inner bark, shredded
- 3.3 Cedar (*Thuja* spp.) outer bark, scraped
- 3.4 Juniper (*Juniperus* spp.) outer bark, scraped
- 3.5 Fireweed (*Epilobium* spp.) down
- 3.6 Goldenrod (*Solidago* spp.) down
- 3.7 Soft wood scraped with sharp blade

Of these, cedar bark is the favorite, if available. Scraped wood is just about the only choice in very wet weather. Favorite choices for scraped wood here in the northeast, in order of importance, are: cedar (*Thuja occidentalis*), juniper (*Juniperus* spp.), tamarack (*Larix laricina*), fir (*Abies balsamea*), pine (*Pinus* spp.), and in the non-conifers, basswood (*Tilia americanus*), willow (*Salix* spp.), poplar (*Populus* spp.), and soft maples (*Acer* spp.).

### 4. Flame-to-flame tinders

In this category, some of the best in the northeast are:

- 4.1 Birch bark (*Betula* spp.)
- 4.2 Milkweed (*Asclepias* spp.)
- 4.3 Thistle (*Cirsium* spp.)
- 4.4 Fir sap (*Abies balsamea*) collected by piercing bubbles
- 4.5 Fine wood shavings
- 4.6 Fine conifer twigs
- 4.7 Grasses
- 4.8 Red conifer needles
- 4.9 Dry leaves

In wet weather, birch bark is by far the best. The only other choices are fir sap, which is very good, or fine wood shavings. You can make small fir sap torches by piercing many bubbles with a stick which has been shredded at the end (by hitting between two rocks).

A very good way to determine the quality of coal enhancer or coal-to-flame tinders, is to use a car cigarette lighter as a testing device. If it keeps going after one touch from the lighter, it's a great coal enhancer. To test flame tinders, touch them with a quick flick of a Bic lighter.

With this, you will be able to discover many more tinders in your area. The subject of man-made tinders has not been discussed here, and the reader is invited to find them. Tobacco is the best coal enhancer around! The only plus for smokers...

Don't forget to carry your matches! It's easier.

Dear Dr. Bourbeau,

An interesting book that discusses tinder from fungi is "Northern Bushcraft" by Mors Kochanski, published by Lone Pine Publishing. If you take the basidiocarps of *Fomes fomentarius* and pick apart the very top fibrous material, dry it and pull apart the fibers it will light with one spark very easily. This fibrous fungal mycelium seems to catch the spark easily and will then smoulder for some time. Its only this very top portion of the fruiting body that works. The *Inonotus* also burns well. There are references about its use for tinder but I do not think I have seen information on its chemical properties.

There is another fungus used by the plains indians, used as a smudge. Once this is lighted it will continue to burn completely for a long time - the same is true for large puff balls. It may be the fine fibrous characteristics of the mycelium allow it to burn so well. In the pacific northwest, *Inonotus* and *Fomes fomentarius* are not common and this other fungus, *Phaeolus*, was used. It probably has the same texture as cotton when dried and after the mycelium is pulled apart.

I will check some of my references and send you those that may apply to answer your questions.

Best regards,  
Bob Blanchette

True tinder fungus - \*Fomes fomentarius\*

The book I got that out of, Adrian Morgan's Toads and Toadstools (1995:108) also says that \*Fomes fomentarius\* and perhaps \*Piptoporus betulinus\* were used in a form of medicine called 'moxibustion' by the Lapps and the Kamchadal of Lopatka. Moxibustion is the burning of a herb (or fungus) over an afflicted spot.

cheers,  
Tim

Must be the same stuff used by the Koreans and Chinese (probably Japanese also) as they also practice moxibustion in traditional medicine. Form the stuff into cones or put on acupuncture needles. Had it done once, not all that bad, and I did feel some better.

Thanks for the info., Tim. On a side note the Chinese use moxibustion also, however they use a relative of our sage or mugwort plants (*Artemisia* sp.) for the process and burn it over accupuncture point or even on top of inserted accupuncture needles.

It would seem then that if this fungus burned like sage, and was easily reduced to powder, it might indeed make a dandy flint and steel tinder and/or a material to keep a coal burning for transport. I'll gather some and dry it and report back on my results.

Mark

Hi again Andre:

My system crashed so I have been "off the air" for awhile.

>

>It is logical that other species of Inonotus would have the same  
>characteristics also. Do you happen to have descriptions of other  
>Inonotus species with their range?

There are other Inonotus that I am familiar with, *I. radiatus*, *I. glomerata* (I think) but no other Inonotus with similar features, they are very different appearing much like the more ordinary looking polypores.

>Fomes has been mentioned as tinder, but no success by me with flint &  
>steel. It does hold a coal though. All mushrooms which hold coals are  
>interesting for survival because they permit one to move about while  
>maintaining their fire. Inonotus is very special because it permits to  
>START the fire!

Ah, I see now. I have borrowed a flint and steel from my wife's father who thought little of the mushroom theory. He believes that, perhaps in this area, the inner bark of the cedar makes the best tinder to start a fire. I have not tried to start one yet though. Btw, how did ancient indians get steel? The flint I understand.

>Maybe you can toss them in an envelope or in a box marked "gift", this  
>sometimes works. Where are you located? Maybe I can get a survival  
>friend from your area to experiment for us... Otherwise, I can surely  
>obtain permission from agriculture Canada. You mentioned New Brunswick.  
>If that's where you are, no problem, I'm in Quebec.

I wouldn't be comfortable trying to pull something over customs. They were very good to me when I transported between NB and Maine. I live in New Hampshire, just prospected in NB for a while.

>> Good luck, and btw, the guy that they found in the alps had some  
>> mushrooms, maybe they were not medicinal at all but were for tinder?  
>>

>I'm am convinced that this would be the case! Maybe we should write an  
>article together to them, telling why we think so.

First I'll have to try starting some fires! *I. Obliquus*, boy it doesn't look to me that it'd start, do you treat it any special way? During WWII they salvaged nitrates from urine, I wonder if tinder could be treated that way, the nitrates would act as an oxidizer.

Professor of outdoor pursuits...eh?

Sounds like what I used to think about doing at the Girl Scout Camp near where I lived ;-)

Dear Dr. Bourbeau,

today I found a webpage devoted to Fomes fomentarius and the primitive  
flint and steel technique. It is maintained by the german society for  
mycology. I remembered that you are looking for information about that. So  
here is the URL:

[http://ix.urz.uni-heidelberg.de/~tstein1/pdj\\_95.html](http://ix.urz.uni-heidelberg.de/~tstein1/pdj_95.html)

your, Ewald Langer

Subject: Swim fishing

Content-Type: text/plain; charset="us-ascii"

X-Mozilla-Status: 0001

Hi Ted;

I've heard about that sort of thing, and also heard of guys that still do dive in the old fashion going to great depths by holding onto a stone ballast until they get to the depth they want then letting go of the stone. That reminds me of another subject in a wierd sort of way that says more about the way my mind works than I'd like to admit.

In THE LAST WHOLE EARTH CATALOG a guy by the name of Ben Masselink had a letter published on hand line fishing and a new twist he put on it he called swim fishing. He was using a Dos Equis reel(an empty Dos Equis beer bottle with fishing line on it) and a white feather jig. It was a hot day so he started swimming and dancing that jig along the bottom of the beach and started catching fish. Apparently he uses fins, mask and snorkel and is able to see the effect of the lure and where to put same in his words " The beauty of swim fishing is that you swim the water the boats can't work. You also work ten times the water that a surf fisherman can because you present the lure parallel to the shore, fishing it all the way." He also comments at the beginning of his article " As you know, spin fishing (where the fishing line pays off the face of the reel) is a very old way of fishing. Even before the invention of the bottle or can, Indians fished in the spin off style using a kind of spin off shuttle. People throughout the world spin fish off bottles and cans." He recomends an Australian plastic reel that I've seen sold in the Into the Wind Kite catalog. My own experience with hand line fishing has been much tamer and without emersion. I've fished for trout, crabs, and crayfish at various times of my life. The biggest fish I've caught was a 15lb. carp with a length of line and a piece

of corn(and released it)

Ted Bailey wrote:

>I prefer to fish with rod & reel. I was a great skin diver as well. Although I used a rubber powered spear gun, I never used SCUBA gear. I would dive over 100 feet down and shoot fish up to 200 pounds and then drag them to the surface. I learned to hold my breath for 2-3 minutes and special free diving techniques by reading the book "The Pearl Lagoon" That was a story about 2 California youths who traveled to Polynesia with their Uncle. They learned to dive using instructions from Pearl divers. The instructions in the book were in fine detail and they worked. In three

months, I went from holding my breath for 30 seconds and diving 20 feet to holding my breath for 90 seconds and diving 60 feet. Over the next several years, I extended that significantly with practice. There is a whole new world under the sea and a great place to gather food and useful materials.

>Are there any other divers in this group?

I was out last summer with my good friend Majella Morin who is also a member of this group. Majella showed me how to dive for suckers using a lasso made from snare wire. He would catch a dozen before I could even get one. He used to feed his dog team with this impressive technique.

I think that the holding your breath techniques might help someone fish for survival, and I certainly would like to hear more about it.

Not too much to it except for practice. For a 2+ minute dive, you need to spend about 5 minutes of slow deep breathing on the surface saturating your body with oxygen. You will know when you are ready. When you start the dive, take a full deep breath and then let a little bit of air out. Do not start the dive completely full. Go down slow. Keep your energy expenditure to a minimum. As you descend and need to clear your ears, hold your nostrils and blow. You must rotate your head into an "up" position when doing so. When you reach the bottom, don't chase fish. Stay still and they will come to you out of curiosity. After about 60-75 seconds, you will start to feel pain in your lungs. This is not because of a lack of oxygen. Instead, there is a build up in the partial pressure of carbon dioxide. Let a few bubbles out and the pain will go away for about 10-15 seconds. You can repeat this about 4-5 times, each with diminishing effects. The ascent should be as slow as the descent. Plan your time appropriately. With practice, you should be able to do 2+ minutes. Hope this helps.

All of the above I did in tropical waters. You will never get me into the frigid waters of Michigan or Canada. - Ted

Don't mean to jump out of line here Ted, but I've exploded a few M-80's myself. Andr , M-80's are usually illegal fireworks, like firecrackers - well they can be bought some places (where I live) with out a blasting license, but they're not considered "Safe & Sane." All of mine have been barrel shaped and had waterproof fuse placement at the center of it's length. Gun-powder filled, it's basically close to a quarter stick of dynamite in effect. Another story (Groan): When I was a kid, our anti-social next door neighbor brought his dog to my yard to do his business everyday (sometimes twice), which I had to clean up after (for years). One day after the deed was done, the pair continued on past my house...until my brother and I tossed an M-80 after them. The shock wave was visible and knocked them both off their feet. I was impressed. They gave us a wider berth thereafter. I also must admit to throwing a perf'ed can of powdered metallic sodium into the city pool, soon after. The depth charge-like explosion (higher than the high dive - it went KaWhuumph!) was impressive and I'm sure could have brought up quite a few fish if tossed in the right place. Chemical supply house's should be possible to find, up your way. Any chemists out there with the correct chemical name for this? Not too primitive, but it'll fit in a expedition pack.

Ted. what's an M-80?

I read that somewhere in Asia, again can't remember where, homemade bombs made from corked bottles are used in the same way to catch fish. Anyone know anything about this? I know it's highly illegal and would never do it, just want to know for survival purposes.

>Ted. what's an M-80?

An M-80 is a very large firecracker. They float, so you have to weigh them down. We never used them in small streams, just the large rivers. They would kill or stun fish at a range of about 10 feet. Great way to get bait for shark fishing. I really don't want to encourage this. I just wanted to make a statement that it is an option if you are desperate for food and have small explosive devices.

When I was a teenager, I lived in Panama and used to work on merchant ships during the summer. In 1968, I took a trip on a Victory ship to Viet Nam. At the mouth of the Saigon River there is a port called Cape Jacques (sp?). Ships would anchor there overnight before making the trip up the river to Saigon. It was imperative that you did not go up the river at night. The entire time we were waiting at the mouth of the river, small U.S. Army boats would circle the ship and throw a hand grenade into the water every 10 - 20 minutes at random locations and intervals. This was done to stun any Viet Cong divers that would approach ships to place explosives. That's all I know about fishing with explosives in S.E. Asia. - Ted Bailey

>I can't get over it! Where the heck do you come up with all these  
>references I have never seen?!

:-)I've just been interested in the same subjects for quite some time. I've been looking for the old knowledge for some time. :-)

SURVIVAL POACHING is by Ragnar Benson and was published in 1980 by Paladin Press 303-443-7250

CaO is quick lime and can cause horrible caustic burns if spilled on wet flesh and not cleaned up immediatly. When CaO is combined with water it reacts and becomes Ca(OH)4 or calcium hydroxide. When mixed with water it expands about three times in volume and gives off a great deal of heat.

"Collect a number of clean onr gallon glass jugs. These must be glass and similar to those used for vinegar, wine or apple cider with a small neck

and secure cap. Clean the jugs thoroughly and then dry them out till they are absolutely bone dry. No moisture can remain in the jug.

You must have about five pounds of clean pea gravel for each jug. Five pounds is about two #6 peacans full. dry this gravel over a low fire, and then pour it luke warm into the gallon jugs. There should be a good healthy inch of gravel in the bottom of the jug. At first it is advisable to test the gravel to see if it is heavy enough to sink the jug. Cork the glass up tightly and float it in a barrel or tub. There must be enough gravel in the jug to sink it without hesitaiton.

Having done this, dry the jug again and carefully pour in one #6 peacan full of CaO in each of the prepared jugs. Replace the cap making sure the jug is sealed airtight. The explosive jug can now be stored safly until used.

I usually take two or three of the jugs with me in the boat. They will arouse no suspicion until used.

To prepare a jug for use, uncork it and hold its mouth just below the surface of the water. Allow about one quart of water to pour in cap the jug quickly and let it sink to the bottom.

Properly done, the jug will go off with a very nice blast in about one minute. The blst will kill fish just about on par with a one stick dynamite charge. Qickly collect the fish as they float to the top with a spear or net.

I don't believe it is advisable to use these lime bombs in less than five feet of water."

There is a bit more mostly that the lime bombs will work at great depths where dynamite won't.

I like Ragnar Benson's other book LIVE OFF THE LAND IN THE CITY AND COUNTRY 1982 also published by Paladin press.

Andre;

I didn't post it to the group, mainly because I wasn't sure it was appropriate on a primitive skills group, even though people barely out of the stone age are using it in SE asia. Also, even though I think most people are honest, and the information is available in print, why should I make it any easier for people that want to break the law ,to do so? Most of the primitive skills limit the chances of taking game on a level that is nearly equal for the game in question. Modern guns, explosives, and techniques require very little knowledge on the part of the user to take game and if broken require specialized knowledge to repair or replecate. Primitive tools, on the other hand require more knowledge both of the materials themselves and the game they are to take. Generally they are quieter as well. Not that mass destruction was not practiced by our ancestors. Game drives either into a fenced off killing area or over a cliff was known to have been practiced nearly everywhere in the world in ancient times. The difference is that every part of the animal was used in the hunters community, surplus was dried and stored, and shared with other villages of the same people. I apologise for preaching.

To answer your other question. Calcium carbonate  $\text{CaCO}_3$  is limestone same as simple lime you might add to your garden. Common limestone is heated to produce quick lime. or unslacked lime  $\text{CaO}$ . Once water is added to that it is slaked lime or calcium hydroxide  $\text{Ca(OH)}_2$ . Quick lime is hard to find but not impossible, it is used in some capacity to clean outdoor toilets. I understand that it has been used by criminals to dispose of bodies. All of this info is from Ragnar Benson's book SURVIVAL POACHING.

Biological poisons are the primitive man's form of explosive. A fish trap or tidal pool with small amount of effective toxin that stuns the fish makes sense for a community or even a single person that will dry and smoke the surplus.

For more info on preserving fish in primitive methods among other arts see SURVIVAL ARTS OF THE PRIMITIVE PAIUTES by Margaret M. Wheat University of Nevada prss; Reno, Nevada 1967 ISBN 0-87417-048-6 It's a paperback approx. 11x14inches and ran about \$10 (U.S.) when I bought it. If you want to post the excerpt from Ragnar Benson's book along with this post to the group be my guest. I just wasn't sure it was appropriate.

I just have a question about these methods of fishing. Why on earth would you do it? I don't doubt the effectiveness or ease of the methods, but there are many drawbacks which I think outweigh the advantages. One, for the use of bombs/grenades/explosives, most of the fish stay on the bottom of the water formation (lake, sea, stream, etc.), so you are getting a relatively low yield percentage-wise. Around 5-10% usually. Second, and I believe this applies to all mass-killing methods, it does a great deal of harm to the ecosystem that you use it in. What is the point of killing 1000 fish at once, having half of them spoil, and then having none left for next spring or whatever. Not to mention that none of these are really a primitive skill :), but that's beside the point.

There is only one good reason for large scale killing of any creature, and that is if you have the facilities for drying and placing into storage the fish for your community. They also did this if the animal population could bear it. It was considered inappropriate to kill on such a large scale for just one person. Remember a hunter in a primitive community didn't just hunt for himself. he hunted for his village and family as well. No one, went away hungry. It's funny isn't it that we call them primitive.

In Southern Alberta, there is an Archaeological site (+ museum) called  
"Smashed-in-head-buffalo-jump" where the Native Americans (Native  
Canadians?) drove the Buffalo off of a 100 metre cliff in mass. Below, the  
cliff, the ground is solid broken bone fragments. I believe they did this  
at the onset of cold weather each year so that they had a plentiful supply  
of meat with natural refrigeration. It's a neat place to visit, but I  
wouldn't want to jump there.

Good point! Primitive people were surviving and feeding their families  
and sometimes other peoples' families. Some have the tendency to over  
romanticize primitive peoples hunting practices. But there are accounts  
of Native American tribes burning down entire forests in a circle just  
to chase the animals to the center of the forest so they could be  
slaughtered. There are also accounts of running entire herds of buffalo  
over a cliffside. So, if one were in a survival situation and had  
multiple mouths to feed, it would not be unlike the first peoples if we  
used an explosive of some sort. On the other hand it would be a shame  
and disgrace to use them for any other purpose. Even if one felt the  
need to test the effectiveness of this technique, they should plan a

group feast of some sort or feed some poor community.

Hi Neal, I see you got on the list. Welcome!

I believe the fishing with explosives thread started when Ralph (I think) mentioned that a couple M-80's might not be a bad idea to include in a survival kit for last ditch fishing. Small and with a high likelihood of obtaining significant calories. They are relatively small as explosive charges go and damage to the ecosystem would be limited. Fishing with dynamite is practiced sometimes in Mexico, I can tell you ("Special Mexican Bait" it was called). I think, chemically speaking, a small metallic Sodium canister might be the most environmentally "friendly" type of explosive reaction. The water would get slightly saltier temporarily and hundred of fish kills would be unlikely, up and down a waterway (which no one here wants - hunters have a big interest in Conservation as a lifestyle). On the downside, DO NOT get metallic Sodium wet, until you're really ready.

Not Primitive, but I believe the topic can stray to modern survival items that at least can be thrown into a backpack to edge one's bet. However, there ARE backpack carried tactical nukes...I can see your point about drawing the line somewhere. I admit, I'm addicted to technology, as a recent widespread prolonged power outage taught me recently with a couple days of 20 below (F) temperatures and lights out. I'm here to learn from these luminaries. I'm filling up my hard disk rapidly with all these topics I'm saving.

-- Chris

>  
I do agree with the above comments. I originated the explosives issue, but  
I do not promote it. I was just comparing this method to fishing with  
oxygen inhibitors. I'm not proud of everything I ever did. I was a  
teenager when I did these things and I didn't do it very often. I was more  
repulsed by watching the indians poison streams.

I prefer to fish with rod & reel. I was a great skin diver as well.  
Although I used a rubber powered spear gun, I never used SCUBA gear. I  
would dive over 100 feet down and shoot fish up to 200 pounds and then drag  
them to the surface. I learned to hold my breath for 2-3 minutes and  
special free diving techniques by reading the book "The Pearl Lagoon" That  
was a story about 2 California youths who traveled to Polynesia with their

Uncle. They learned to dive using instructions from Pearl divers. The instructions in the book were in fine detail and they worked. In three months, I went from holding my breath for 30 seconds and diving 20 feet to holding my breath for 90 seconds and diving 60 feet. Over the next several years, I extended that significantly with practice. There is a whole new world under the sea and a great place to gather food and useful materials. Are there any other divers in this group?

>I can't get over it! Where the heck do you come up with all these  
>references I have never seen?!  
:-)I've just been interested in the same subjects for quite some time. I've  
been looking for the old knowledge for some time. :-)  
SURVIVAL POACHING is by Ragnar Benson and was published in 1980 by Paladin  
Press 303-443-7250

CaO is quick lime and can cause horrible caustic burns if spilled on wet  
flesh and not cleaned up immediatly. When CaO is combined with water it  
reacts and becomes Ca(OH)<sub>2</sub> or calcium hydroxide. When mixed with water it  
expands about three times in volume and gives off a great deal of heat.

"Collect a number of clean onr gallon glass jugs. These must be glass and  
similar to those used for vinegar, wine or apple cider with a small neck  
and secure cap.Clean the jugs thouroughly and then dry them out till they  
are absolutely bone dry. No moisture can remain in the jug.  
You must have about five pounds of clean pea gravel for each jug. Five  
pounds is about two #6 peacans full. dry this gravel over a low fire, and  
then pour it luke warm into the gallon jugs. There should be a good healthy  
inch of gravel in the bottom of the jug. At first it is advisable to test  
the gravel to see if it is heavy enough to sink the jug. Cork the glass up  
tightly and float it in a barrel or tub. There must be enough gravel in the  
jug to sink it without hesitaiton.

Having done this, dry the jug again and carefully pour in one #6 peacan  
full of CaO in each of the prepared jugs. Replace the cap making sure the  
jug is sealed airtight. The explosive jug can now be stored safly until  
used.

I usually take two or three of the jugs with me in the boat. They will  
arouse no suspicion until used.

To prepare a jug for use,uncork it and hold its mouth just below the  
surface of the water. Allow about one quart of water to pour in cap the jug  
quickly and let it sink to the bottom.

Properly done, the jug will go off with a very nice blast in about one  
minute. The blst will kill fish just about on par with a one stick dynamite  
charge. Qickly collect the fish as they float to the top with a spear or  
net.

I don't believe it is advisable to use these lime bombs in less than five  
feet of water."

There is a bit more mostly that the lime bombs will work at great depths  
where dynamite won't.

I like Ragnar Benson's other book LIVE OFF THE LAND IN THE CITY AND COUNTRY

1982 also published by Paladin press.

Touch of the Bear

Andre;

I didn't post it to the group, mainly because I wasn't sure it was appropriate on a primitive skills group, even though people barely out of the stone age are using it in SE asia. Also, even though I think most people are honest, and the information is available in print, why should I make it any easier for people that want to break the law ,to do so? Most of the primitive skills limit the chances of taking game on a level that is nearly equal for the game in question. Modern guns, explosives, and techniques require very little knowledge on the part of the user to take game and if broken require specialized knowledge to repair or replecate. Primitive tools, on the other hand require more knowledge both of the materials themselves and the game they are to take. Generally they are quieter as well. Not that mass destruction was not practiced by our ancestors. Game drives either into a fenced off killing area or over a cliff was known to have been practiced nearly everywhere in the world in ancient times. The difference is that every part of the animal was used in the hunters community, surplus was dried and stored, and shared with other villages of the same people. I apologise for preaching.

To answer your other question. Calcium carbonate  $\text{CaCO}_3$  is limestone same as simple lime you might add to your garden. Common limestone is heated to produce quick lime. or unslacked lime  $\text{CaO}$ . Once water is added to that it is slaked lime or calcium hydroxide  $\text{Ca(OH)}_2$ . Quick lime is hard to find but not impossible, it is used in some capacity to clean outdoor toilets. I understand that it has been used by criminals to dispose of bodies. All of this info is from Ragnar Benson's book SURVIVAL POACHING.

Biological poisons are the primitive man's form of explosive. A fish trap or tidal pool with small amount of effective toxin that stuns the fish makes sense for a community or even a single person that will dry and smoke the surplus.

For more info on preserving fish in primitive methods among other arts see SURVIVAL ARTS OF THE PRIMITIVE PAIUTES by Margaret M. Wheat University of Nevada prss; Reno, Nevada 1967 ISBN 0-87417-048-6 It's a paperback approx. 11x14inches and ran about \$10 (U.S.) when I bought it. If you want to post the excerpt from Ragnar Benson's book along with this post to the group be my guest. I just wasn't sure it was appropriate.

Ben, thanks for such a great post on fish poisons. I'd sure like to have the scientific names of all the plants you mention though, if you have them. In different parts of the world, as you know, there can be so many different names for the same plant or a same name for so many different plants as to make things very confusing.

Again, thanks. Looking forward to see if any of the plants you mention or botanical relatives of them could be applicable here in the north.

AndrÈ

Good point. Common names can be misleading. I wish I were more knowledgeable on scientific names. I'll do the best I can. Maybe I'll run these plant names past my friend Christopher Nyerges. He is the plant expert and see if he knows the scientific names. I need to contact him anyway and twist his arm to join our group. We're going to need a good plant person sooner or later. By the way, how many do we have in the group with knowledge of medicinal and edible plants? Please step forward, so we can pick your brains from time to time. I do OK with plants and know enough to survive, but there are so many I know that know so much more than me.

Hi all,

I just joined the list and have been reading the thread on fish poisons. I once met a guy who claimed he fished this way with crushed mullien (Verbascum ???) seeds. Has anyone else ever heard of such a thing?

I was just collecting some California buckeye seeds to roast them, having heard they were edible, and I also read that they are full of saponins which can be used to stun fish. I haven't tried it myself, and the seeds are still in the fridge. Buckeye does make great fire sticks, though, and it's a feast for the eyes as well.

Subject: Fish Poisons

Content-Transfer-Encoding: 7bit

Content-Type: text/plain; charset=us-ascii

X-Mozilla-Status: 0001

Hello group! I e-mailed Christopher Nyerges at the School of Self Reliance in the City of Angels and asked him to help us out on the scientific names of the fish poisons I gave out the other day. He not only supplied me with some of the names but gave me some other info I thought I'd pass on. Here are portions of his note in quotes below and some additional info I have found out since then:

" Hi Benjamin.

As to your plants poisons: A few I will need to look up. I would be happy to provide you with an article about poisons and how to use them.

White Camus Lily -- I have to look up, but I don't think we're dealing with anything rare here. In Calif. anyway, you're probably referring to Death Camas, *Zygadenus* sps. Otherwise, you'd need to tell me range so I know what area of the country you've found this in. I am unfamiliar with that common name.

Devil's Shoestring: Again, this is a common name that I am not familiar with, and it could be a local common name. I suspect you might be referring to *Hedera helix*, common English ivy, whose leaves and berries contain glycoside hederagenin, which could cause death. A related plant-- probably in your neck of the woods, is *Aralia spinosa*, sometimes known as Devil's walkingstick, has berries that could kill if eaten in quantities. Could you be referring to that? [As far as Devil's Shoestring I found out it is actually *Tephrosia virginiana*, a perennial herb and legume commonly used among the Catawba people to treat rheumatism. It is also known as Goat's Rue. It grows in NC and SC from the mountains to the coast. The correct reference was found in Frank G. Speck's book, *Catawba Medical and Curative Practices* (1937). ---Benjamin]

Horse Chestnut and Buckeye are both the same thing: Buckeye, the Ohio state tree, and there is also a California buckeye. The genus is *Aesculus*, referring to the glycoside esculin. Its a good fish stupefier, and the nuts can actually be leached like acorns. I have done so. However, esculin is not noticeable like tannin (bitter), so it's difficult to know when the leaching is done. Most folks just leave it alone.

Polk Sallet: It's a poisonous plant alright, but everyone from before slavery days ate it. The poison -- I don't seem to have its exact name at my fingertips -- is water soluble meaning you cook the greens, pour off the water, and cook again and then you can safely eat it. We're speaking of ordinary Pokeweed (*Phytolacca americana* and related sps.). Some folks see the word Sallet and they think it means Salad. Wrong! Sallet is, if my memory is right here, from an Old English word and it refers to cooked greens. Anyway, death can occur if you try to eat this and don't do it right.

Turkey mullein is restricted to the Southwest, I believe. I don't have the Latin name handy, but it is in the spurge family, and it grows in low, mounds. The leaves resemble mullein leaves, but are toxic. I have used it, thrown in pools, to stun fish.

Wild Cucumber is also known as Manroot, and it is the *Marah* genus. There is a chapter on this in my Wild Food book. Do you have a copy of the book? If not, I'll send you one. Though my book doesn't say this, you can mash the root and throw into pools to stun fish. I have not done this.

I hope this helps.  
Christopher Nyerges  
nyerges@earthlink.net  
<http://home.earthlink.net/~nyerges/>

Expect ONLY the very best  
and also  
Prepare for the very worst"

-----  
Thanks to Christopher for the help. He does have some excellent books on plants and a workbook on survival skills. Just check out his homepage for details. There are also some nice links there. And if you're in his neighborhood he conducts some fine classes. I've been twisting his arm to get him to join us. He would be great to have for his plant knowledge alone. He is also skilled in many other ways.

I have also heard of this and can't ever remember what plants would be toxic  
enough for this. Anyone know?

Well, I just did a little test. Neither mullein seeds nor leaves seem to have any effect on fish.

That's a new one for me, Jeff. Thanks for the post, hope someone else can answer this one or help us research it further. To help the research, the scientific name of the Mullein plant is Verbascum thapsii. This is a very common plant and it would be very useful to find out more about this.

You may be talking about the turkey mullein plant. It is in the gourd family and grows in the Southwestern U.S. Christopher Nyerges uses this entire plant for fish poisoning. The scientific name is Eremocarpus setigerus. Hey, even I can come up with scientific names thanks to Chris's great reference to the Ethnobotany Cafe!

That is very possible though the guy who told me about using mullein was discussing the mullein that grows around here (Maine) when he talked about it. He said you just crush up some seeds and throw 'em in. I am trying an experiment with leaves as its darn hard to find mullein seeds this time of year. Leaves don't seem to work. I have a few seeds and may try them. The guy also said the seeds only stun the fish. They are paralyzed for a while. He cautioned that if I were to try it I should not do it on a sunny day or all the fish would die of exposure as they floated to the surface.

Please keep me posted on your success. I have used common mullein in many applications (Inhaling burning leaves for congestion relief, placing fresh leaves in shoes for soothing the feet, dried stalks for friction fire making, seed heads dipped in bee's wax for torches, etc.), but not as a poison.

>Andr 

According to the descriptions in "Identifying and Harvesting Edible and Medicinal Plants" by Steve Brill (ISBN 0-688-11425-3) and "Indian Herbology of North America" by Alma Hutchens (ISBN 0-87773-639-1) I believe I used *Verbascum thapsus*.

I placed several of the first year leaves (still green even after the cold) in a tea ball. I was sure to tear them up well. I placed them in a fifteen gallon aquarium with two Silver Dollars (dunno their scientific name. Related to piranha though. Can be bought in any pet store), two Red Tailed Black Sharks (ditto on the scientific name), and several snails both tropical and MAine natives. No effects were observed after 40 minutes.

Then I crushed up all the seeds I could get and placed them in the water directly. Ended up being about 15 and mullein seeds are small. I crushed up the seed hulls and any remaining seeds I didn't notice into the tea ball too. Nothing happened after another 40 minutes.

The guy who told me he fished with mullein seeds said he uses a teaspoon of crushed seeds in a small frog pond size pond. With that concentration it seems this should have done it. I will try and contact him and get further info but no promises.

Right now I am going with *Verbascum thapsus* doesn't work well for catching fish.

But.....

To complicate things a bit more I have an old book that has a paragraph about fish poisons. The book was published in 1956. It is "Living off the Country" by Bradford Angier. No ISBN but it was published by Stackpole Books and has a Lib of Congress Card Catalog number of 56-11267.

This book quotes another book by the same author called "How to Build Your Home in the Woods". It says referring to capturing fish:

One procedure is to crush the leaves and stalks of the mullein or fish weed, *Croton setigerus*... The fish therein, momentarily narcotized, will float to the surface..."

It also mentions the soap plant (*Chlorogalum pomoidium*) and southern buckeye (*Aesculus pavia*).

Now, turkey mullein is *Eremocarpus setigerus* yet the mullein referred to in this book is *Croton setigerus*. Anyone know if there was taxonomical change between 1956 and present in regard to this plant or what?

Dunno...Just thoughts...

Jeff

Here are some fish narcotics straight from a book (SAS survival),

Derris: Occur in se asia to australia. N/a to everyone but powder the roots and chuck it in

soap plant: occurs in the usa in dry open scrubland. it ois a narrow grass like leaves with white star like flowers. crush the buolbous root and chuck in the water.

I guess these are not the sci. names but its all i got.

I wonder what plant they mean? That's what I hate about some survival books. When they don't give any more details than that it makes me wonder if they have even tried it. I mean, there are many plants you can get "soap" from. More properly said, many plants contain saponins.

Plants that contain saponins for cleansing would be a good subject. If anyone is interested, let it be known and I'll post a few notes on the subject.

RESPONSE; Hi -- today is Tues. 12/31. I'm talking to Dr. Borbeau, correct?  
Benjamin passed along some data of mine and I'm glad it has been useful to you.  
I have to apologize about the slowness of my responses, since I'm still in the  
the stone age of writing letters and talking on phone. And my computer is so  
slow that I could do my laundry with a rock while I'm waiting. for things to  
come up. Anyway, I have quite a bit of practical knowledge on fish poisons  
that I could share. Should I write it up and mail it? It would be lengthy to  
e-mail it all. Plus, If I take the time, I can make a chart and compare the  
various poisons. You should know, of course, that the use of fish poisons is  
illegal everywhere in U.S and prod probably in Canada too. Still, it is good  
to know for emergencies. Though it has been a few years since I have actually  
tried some of these, I keep good notes. Also, I have read what other authors  
say on this subject. Bradford Angier, for example, makes major mistakes when  
he writes on this subject, probably because he was just inaccurately copying  
from some other books. I actually wrote to his publisher and told them, but  
they simply said that Angier sells a lot of books, and that was good enough for  
them. Anyway... Let me hear from you. Honestly, it would be quicker if you  
sent me a postcard or letter at Box 41834, Eagle Rock, CA 90041, since I  
generally answer my mail quicker than these e-mail messages. Thank you for  
contacting me. If I can be of more help, I will do the best I can. Give my  
regards to Benjamin. Christopher Nyerges.

>Hi Chris,

>

>Thank you for sending Ben that wonderful information on fish poisons

>which he passed on to us with your permission.

Sorry to beat this topic do death still further but...

Looking at the plants we have discussed I do not believe any grow in Maine. Does anyone know about any plants that grow in Maine that can be used to stupify fish?

Jeff

Forwarded- Text from Thomas E. Elpel

It appears that the fish poison discussion started long before I  
joined the group. However, I beleive I have some new information, so  
here  
goes:

I have done extensive studies of patterns in plant properties  
and  
uses. One pattern I noticed is that plants that are used as a poison to  
stun fish almost always contain a substance called "saponin". The  
following three paragraphs are adapted from my Herbal Field Guide to  
Plant

Families:

Saponin is a glucoside poison, but it must enter the bloodstream  
to  
be toxic. (A glycoside is a sugar combined with an non-sugar  
(a-glycone)  
compound. It is called a glucoside when the sugar is glucose.)

Saponin normally breaks down in the digestive system, making it  
harmless. Fish, however, directly assimilate the saponin into the blood  
stream through their gills. Adding a significant quantity of an herb  
with  
saponin to a small, still pond may effectively stun or kill the fish (I  
haven't tried it yet), without harming the fisherman who eats them.

Plants that contain saponin can usually be worked into a  
"lather",  
and are typically used as soap substitutes. Specific plants that  
contain  
saponin include: yucca root (Yucca spp.), buckbrush flowers and berries  
(Ceanothus spp.), snowberries (Symphoricarpus spp.), bouncing bet

(Saponaria officinalis.)

I could not find any material on the properties of buckeye (Aesculus), except that the fruit is used as a fish poison and many species are known to be edible after leaching to remove the bitterness. This bitterness also suggests the presence of saponin. If you looked through enough sources there is a high probability you would find one that lists saponin as a substance in buckeye.

Contact me if you are interested in my Herbal Field Guide to Plant Families. I am closing out the remaining copies of the first edition for \$15 (rather than \$20). The book focuses on the common patterns of identification and constituents within plant families. It is a way of studying plants as whole groups, rather than as individual species. The book covers 100 of the approximately 300 families found in North America, which includes the majority of the families in the frost belt. It is only minimally useful in the southern states where hard freezes never occur.

I am working on a key for the second edition, due out in the spring. I will make the key available separately for anyone who has bought the first edition.

I am following up my last letter where I wrote:

> I could not find any material on the properties of buckeye  
>(Aesculus), except that the fruit is used as a fish poison and many species  
>are known to be edible after leaching to remove the bitterness. This  
>bitterness also suggests the presence of saponin. If you looked through  
>enough sources there is a high probability you would find one that lists  
>saponin as a substance in buckeye.

Today I found a database on the web  
(<http://www.axis-net.com/pfaf/plants.html>) that mentioned saponins in  
buckeye. I only checked one of the several species covered there, but I  
expect that most of the others contain saponin as well.

Noticing patterns in plants will help you predict the properties of  
other new plants you encounter.

Hi. I have heard of the use of rotenone ( a biodegradable natural pesticide) to stun fish for collecting them. This was done by (I believe) the Yanomamo tribe, and possibly other South American natives by crushing a certain liana and throwing it in the water.

I have also read in a book that the indians in the southeast US used a plant for this purpose - however, the book did not specify the plant. Someone suggested that it may have been the corm of the Jack in the Pulpit - Anyone with knowledge on this please respond.

Also - I read that there is no effect on humans from eating fish harvested in this way - but I gotta wonder if that's true.

Howdy!

>Hi. I have heard of the use of rotenone ( a biodegradable natural  
>pesticide) to stun fish for collecting them. This was done by (I  
>believe) the Yanomamo tribe, and possibly other South American natives  
>by crushing a certain liana and throwing it in the water.

I don't know about the Yanomamo, but the practice is fairly common. The material I saw came from the pounded root of a Plant I never had an identification for. It was a vine. The pulped material was tossed into a very slow moving stream or a pond and the fish would surface down stream or be washed into a net set in place by the fishermen. I saw this done by Brazilians at one of the gold mining villages I visited and by native peoples I met in various areas.

Rotenone is available in some gardening stores as a natural insecticide.

>I have also read in a book that the indians in the southeast US used a  
>plant for this purpose - however, the book did not specify the plant.  
>Someone suggested that it may have been the corm of the Jack in the  
>Pulpit - Anyone with knowledge on this please respond.

We use a plant that is locally known as Wild Cucumber. The root is large, often 6"-10" in diameter and may be hundreds of feet long. The vine it kicks out has grape like leaves and round, spiny fruits. I'm sorry but I don't have my notes up here so I can't tell you the real name, it is sometimes called "Manroot" (not "Mandrake").

It is crushed, and the crushed material is tossed into a stream much as I described above. It seems to cause the fish to suffocate. If they aren't harvested, or wash out into faster water, they recover and swim away.

I've heard of dogwood being used this way but I have no experience with it.

>Also - I read that there is no effect on humans from eating fish  
>harvested in this way - but I gotta wonder if that's true.

I dunno, I've eaten lots of fish taken in this way. Never had a problem. I've never heard of anyone having a reaction. But this numbness in my tongue..... hmmmm.

>Rotenone is available in some gardening stores as a natural insecticide. We had a lake in E. Tx. and Dad decided (from expert advice) to rotenone the lake, to clear out the excess fish, ect.

We enjoyed a wonderful fish fry. Don't recall if fishing improved. We later fertilized the lake and then had to harvest the excess muskweed that began choking the lake.

What about the technique of dropping a tree in a water way(weeping willow comes to mind). Does the tree kill the fish, or is the obsorption of 0-2 the reason one could then harvest fish?

I have read of crushed buckeyes or crushed black walnut hulls. Never tried it though. Seems like it would take a lot of work to get enough Jack-in-the-Pulbit corms to do any good.

Subject: Food and it's Preservation

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

Hi all, Here's another paper bomb! :) :)

To start with I'd like to throw out something that may be debateable. I'd like to see a lot of comments on this. Especially if someone knows different.

As far as I can determine the flesh of all mammals, all reptiles, and all birds is free from any poisonous content and safe to eat. But NOT the flesh of any fish! I believe that the flesh of any North American fresh water fish is safe, but again, please, let's check this one! At the Jungle Operations Training Center in Panama, they told us that if it looks like a fish, it's safe, if it don't, don't touch it.

By poisonous, I mean actually toxic, that is, containing a poison.

Now, "safe to eat" doesn't mean that the meat may be eaten with no ill effects. It merely means that the flesh itself contains nothing which will be poisonous to a normal adult human being.

Many animals are hosts to parasites which can be fatal to man if they are introduced into his body. The best example I can think of here is Trichinosis, which is probably the reason for the Jewish ban on eating pork.

Consequently, no flesh is absolutely safe to eat raw, even in an emergency. However most parasites and their eggs are killed by heat, so cook it first!!! I say most here, because there are some spores that can't be killed outside of pressure cooking. (I remember being told this, but am drawing a blank trying to remember what ones. Anyone got the names and distribution?)

We all know about rotten meat. It's not very good to eat. Either tasting or health wise, so now, how to preserve.

The preservation of meats for long periods can be accomplished by smoking and sun drying, and by brining and cooking in fats. If the climate permits, you can freeze it too, though I hope you aren't in a survival situation in that kind of climate. Not fun!

#### Smoke/Sun Drying

The meat to be used in this process must be freshly killed. Cut off the fatty parts (they'll get rancid, save them for rendering), and then slice the meat into strips no thicker than 1/2 inch and no wider than an inch. I'd suggest no thicker than a 1/4 inch. The thick stuff takes longer to dry and if it isn't completely dry when you store it, it'll rot! Yuk!

Now, thread it on a wire or fresh cut cane, or willow stick with the bitter bark stripped off and washed. (save the bark for the headache later. :) ) Hang the canes or whatever else you've used over a low, slow fire that's making thin blue smoke. Don't let it get in the fire, you're only trying to dry the outside right now, not cook it. This might take from an hour to a day.

You can let the meat dry completely in the smoke and fire and that may be a good idea in the winter. The other way is to hang your meat in the sun to finish. The reason you need to dry the surface is to protect the meat from blowflies that'll lay their eggs on the meat if it's wet.

Now, if your intention is a good plate of maggots...

When the meat is thoroughly dry, it needs to be stored on a bag with an open weave to keep condensation (and therefore mold) down.

The above works for just about everything except fish. If the fish is known to be safe to eat, fillet it (the big ones), or hang it by the tail (the small ones) with a small stick stuck just behind the gills to spread the body cavity.

Filletts may be flakey and not hang well if so, use a hot clean rock. Same reasoning as with meat. Dry the surface to stop blowflies. Fish does need to be dried quicker than most other meats as it spoils quicker.

With all of these processes you're working against putrifaction. Best to get it done as soon as possible.

BTW don't try to build a smokey fire, especially by adding green wood or leaves. What you'll get is meat with all the essential oils from the green wood or leaves cooked into it. Doesn't taste so good. All you need is the thin blue smoke from a normal fire.

## Brining

Meat, cut into small pieces of about half a pound each and put into a strong solution of salt and water (brine) will keep almost indefinitely. My grandfather's brine used to be strong enough to float a fresh chicken egg. Remember to keep the meat **BELOW** the surface of the brine. We used to float a piece of wood on top of our brined olives to keep them below. I'll post or email that process too if someone wants it. It uses lye, so it's not really primitive.

## Cooking in Fat

Meat can be preserved five to six days in summer by preliminary cooking in fat, and then allowing the meat to remain in the fat in which it was cooked. The heat of cooking sterilizes the meat and the fat seals the meat safely away from bacterial infection.

I've heard of preserving things longer in fat, but don't know the how and why of it.

Now...Iffen ya got some hick'ry and some salt and some sugar, 1/2 Cup of salt, 1/2 cup of sugar and 1 quart of water make a brining solution. Brine meats (not fish) 6 hours to overnight. Rinse, pat dry with a paper towel, and allow to air dry for an hour. It should have a kind of glazey surface now (the pellicle). Smoke it for three to fours in hickory (or fruitwood ...) smoke and let it dry in the sun or your oven. This recipe is basic and is provided so that you can get used to smoked foods before you have to live on them. :) :) :)

## Fruits and Vegetables

These don't need the smoke, but do need to be rinsed. Sun dry just about any fruit or vegetable. Maybe even use the hot flat rock method, but watch out for smoke. A lot of fruits and veges just don't take to smoking. They taste terrible. Besides any that taste good when you smoke them will give you lung cancer. They also do need to be screened if at all possible to stop blowflies. If not, at least keep the dried food in a loosly woven container for good air circulation and check it often for undesirable additions.

## Fancier Stuff

Now that you have dried fruit and veges and meat, it's time to make pemmican. Grind the dried meat and anything else you'd like with it and mix it with fat to bind it. The fat is good for producing heat in the winter and I'm reading that it's the fats in stuff like sausage that binds the meat and stuff togetner when you heat the mix again. Haven't tried making sausage yet, but if someone has please tell us so we know whether or not to smoke our pemican.

If you have the time. Dig a pit for your fire. Dig a trench from the pit to the place you'll build your smokehouse. Cover the trench with bark, stones, dirt, etc. so the smoke and heat don't leak out. The trench needs to be slightly uphill toward the smokehouse end. Now, over the smoke house end of the trench build a thatch hut with a shelf for meat.

Oh, don't know how to build a thatch hut? Sounds like a nice topic for a post.

Merv, who gained weight in the last 'survival' situation he was in! :)

There are indeed several species of fish that contain poison. I'm surprised they told you that at JOTC. I lived in Panama (in Gatun, just a few miles from JOTC) as a boy and fished almost every minute of my free time. On the Pacific side of the isthmus, you can catch a small fish that looks like a Snapper, but it has a soapy film over it's outer skin. It is slippery to hold and the natives will tell you not to eat it. On the Atlantic side of the isthmus, you have to be careful eating large Dogtooth snapper and Barracuda because both of these fish eat smaller reef fish which have eaten a poisonous coral of some kind. There are multiple guidelines I heard to avoid these toxins. One is to avoid eating barracuda longer than 36 inches. The other is to let the fish lay on the dock for 30 minutes and if the flies don't show interest on the fish, then it is safe to eat. A similar situation holds true in the waters of Florida. I can't remember the name of the toxin, but it is fairly well known in the tropical Atlantic and causes paralysis.

By the way, In the Panama Canal, the sun rises in the Pacific and sets in the Atlantic. Boy was I confused when I moved to the USA.

True, for City Guts....but fetid meats were eaten by various native  
peoples.

Come Spring thaw and the indians were pulling buffalo meat from melting  
ice, eating it on-the-spot ."Aged" salmon was highly regarded by indians  
of Northwest Pacific coast(Nez Perces).

Spices were used to help mask the flavor/odor of meat gone bad...but  
still needed eating.

I recall my Dad telling me of his merchant sailing days, when a storm at  
sea forced the cooks to slaughter all the injured, live stock, and for  
several days the crew enjoyed meat, and lots of it.

But after a few days, meat began turning. Mold, maggots, ect. Crew would  
not eat at first....but once they realized that that was all they were  
going to get, they began picking out the "stuff". To his dying day, Dad  
never minded scrapping food off floor and eating.

Controlled aging is what makes good beef, hams, ect. Of course, proper  
cooking keeps you from getting sick(most of the time).

B-MAN Rich,

Just a small point (except I'm wordy). Sorry to digress. The Nez Perce are a hell of a tribe (the only tribe to have their own breed of horse - the Appaloosa, they prospered during the gold rush by selling supplies to the Sourdough's, they saved Lewis & Clark's lives when they found them starving (they contemptuously threw the puppies they were reduced to eating at them, hitting one man in the chest - then they fed them). I could go on for quite some time. One thing though, they aren't coastal Indians (as far as fish goes, they eat salmon, both 'kokanee' sockeye and big chinook - as well as a varied assortment of other salmonids, like "Steelhead" which they harvest from great rivers like the Lochsa, Selway and Clearwater in Idaho). Their ancestral "summer home" was in the Blue Mountains of Northeastern Oregon near present day Enterprise, OR (they were removed, placed on reservation but as of late have been asked to please return, because they're money-makers and would improve the economy). The rest of the year they lived near me, in Idaho in the Bitterroot Mtn.s, where I live. I summer in their homelands and the scenery looks like Yellowstone Park, including plenty of primitive hotspots. You're welcome out anytime, I can be convinced to give the grand tour at the drop of a hat (meet some Nez Perce) and it's a beautiful Sportman's Paradise. I'm aware of one coastal NW tribe, the Haida that maybe the ones you mean. They were quite the seafarers. Impressive you know about the Nez Perce down on the Gulf Coast. That's worth a beer

out here and a place to stay. Right now it's all snow shoveling though (I just did my roof)...

Chris

Oops, I just thought of something. On the pit fire smoker, I forgot to cover the pit with the fire in it. I'd make the pit deep and small in diameter so the rocks I could find in the area would cover it. Seal not too tightly with dirt. You might want a low hole to feed wood and for draft.

The Tripods Benjamin mentioned are great too. I forgot about them, though they're one of the best for fish. Just watch that you don't heat the wood enough that you drive the essential oils out of it into the meat. (Unless you like the taste.)

Peeling the sticks where the meat is resting is a good thing to do too. Also Benjamin mentioned hanging which is probably the best method. Just be sure that the meat is dry before you pack it away. (Thicker meat takes longer.)

Happy smoking.

Merv

Good post, Merv! I like making a tripod with horizontal sticks lashed at different heights and placing near a fire and hanging strips of meat on the horizontals. If I have a lot of meat I make two tripods and lash poles between them. I love doing fresh trout this way. Just cut them open, gut them, leave the head on, break the back and hang them meat side outward toward the fire. I prefer smoking as opposed to sun drying. It's quicker and it keeps insects away from your food.

More on the tripods I mentioned. Merv caused me to remember. Fish smoked  
this way is tasty if cooked enough and eaten then. You do need to dry it  
more for long time preservation. It then becomes pretty awful to the  
taste, but is still very nutritious. You can grind dried fish to a  
powder and presrve it this way and add it to stews. This makes it more  
palatable.

This is how I smoke my bacon, hams, fish and beef jerky.

I've got a tent about 6 feet high by 6 feet wide by 8 feet long which is closed on all sides except for a small closeable door at the bottom front and a crack at the top back. I suspend my meat from a rack at the back top of the tent (rack size is 5feet by 3 feet), about 5 feet from the ground. When I'm in the bush I make a tent from a tarp or from natural materials (rotten logs, sod, moss, bark etc) of about the same dimensions (sometimes a bit smaller), but always 6 feet high with meat 5 feet high.

Then I start a small fire at the front of the tent. Above the fire there is no meat: it's further back. I throw a few dry sticks on the fire to get it going, but never more than 1 foot high. Then I throw finely split green wood on the fire and watch the tent from afar. If smoke spills out the top back, everything is fine! If not, I go adjust the fire, which is about every half hour or so. Sawdust instead of wood works better, but is less primitive, so to practice I do it the hard way. Usually I just have to move the half burnt pieces to center, add a couple of small pieces of dry wood, and a few pieces of green wood.

For beef jerky less than 1/2 inch wide, it is ready in about 12 to 14 hours. The meat is dry and smoked and delicious. If it does not crack when it bends, it is not ready and will mold. I ate today the last of beef jerky I had smoked last summer. It was stored on a shelf in the kitchen, simply wrapped in a brown paper bag, nothing else, and was still delicious, so it works.

VERY IMPORTANT! Not all woods will work for this technique! Some woods (especially conifers) give up very nasty fumes that will ruin your meat. Woods I know for sure that work well are the following, in order of

preference:

1. Apple and other woods from the Rosaceae family (hawthorn etc.)
2. Hickory
3. Maple
4. Alder

This process both dries and smokes the meat. It's called heat smoking. This is my favorite way of drying meat, cause around here the sun never seems to shine long enough to dry meat, and also there are so many flies- once a squirrel I had hung up without smoke was full of fly larvae when I came back with firewood in my arms 5 minutes later.

I hate worms in my grub!!

Hope this is useful.

AndrÈ

Hi Bill,

There are as many recipes for smoking as there are chefs.

Here's mine. Sorry, I'm a chef and chefs don't measure!

Enough mixture of oil, soya sauce, red wine, and brandy to cover the meat (just about any proportion will work).

Salt and pepper to bring out the flavor of the sauce.

Tabasco, chili pepper, or cayenne pepper for desired strength.

Dry mustard for beef.

Garlic for pork.

Herbs for poultry.

Maple sugar or pineapple juice for hams.

Sometimes some curry powder or a little bit of cinnamon for variety.

Soak the meat in the mixture and put it in the fridge. Leave until ready (usually overnight). You can test for flavor by frying up a small piece and tasting. That's close to what it will taste later. If it's not strong enough, leave it longer.

Now drain on paper towels and smoke it... then send me a piece by snail mail!

Enjoy!

I've used juniper (use fresh juniper twigs) for beef when hot smoking, it should work fine for other red meat as well.

There's an article at

- [100-mile footrace](#)

about a group of 3 American Indians who came to America from South America for a 100-mile footrace, placing 1st, 2nd, and 5th.

Sneaker companies tried to get them to wear their sneakers for the race, but they threw them out and wore sandals made from tires during the race.

Some excerpts:

"Ken Chlouber was laboring up a dusty dirt road about 25 miles into the Leadville Trail 100 ultramarathon last weekend when he was passed by two other runners.

Chlouber looked over at the pair and then down at their feet, which were bare except for sandals made out of used tires, leather thongs and nails.

...

The Leadville Trail 100 is considered one of the most grueling in the country because nearly all of the race is run at elevations higher than 10,000 feet and twice goes over 12,600-foot Hope Pass. Only 138 of the 294 runners who started the 11th annual race at 4 a.m. Saturday finished the course.

...

This year's winner, Victoriano Churro, wanted to be on the team badly enough that he apparently lied about his age, fearing they would think he was too old. He had told them he was 38, the same age as his running mate, Chacarito.

"When he finished the race, he came to the medical tent and I heard the doctor asking him his age," race director Merilee O'Neal said.

"I heard him tell the doctor he was 55." Churro then admitted his lie to Williams and Fisher.

Churro and Chacarito, who ran in tandem nearly all the race, started out wearing running shoes they had been given.

They discarded the shoes at the May Queen aid station 13 1/2 miles into the race, opting for their sandals instead. They declined offers of rain ponchos despite periodic showers. "

I think this message was addressed to Thomas, but I too have designed a  
unique way of making sandals with tires (different from his), but cannot  
describe it on this medium. Perhaps I will publish it somewhere... any  
suggestions where?

As requested, here is the article on making tire sandals. Some details of the pattern may be a little difficult to grasp without the pictures, but most of it should be clear. To see the illustrations check out the Summer 1995 issue of BackHome magazine, or contact me directly at [tomelpel@3rivers.net](mailto:tomelpel@3rivers.net) for information on my Field Guide to Primitive Living Skills.

I am concerned about the length of this document (2800+ words, 12,000+ characters); if anyone has trouble down-loading it, or doesn't want to receive such large pieces of mail, then write to the group and we can discuss an appropriate size for future documents.

Tire Sandals

Soles for Primitive Footwear

By Thomas J. Elpel

I'm hard on shoes. It's not uncommon for me to go through half a dozen pairs of shoes, or more, each year. I maintain an active lifestyle, hiking, playing, camping, and working. Water wears out a shoe quicker than anything else. A few trips in and out of the creeks, puddles, and swamps, and they just come unglued.

If I do not happen to dissolve my shoes in water, then I wear out the soles on gravel. It has always amazed me that tire companies can manufacture a tire and warranty the tread for some 50,000 miles, yet I can wear out the sole on any ordinary shoe in less than a year. How come we cannot buy a shoe with a 50,000 mile warranty?

Really, I have never been quite satisfied with conventional shoes, and it's not just because I wear them out so easily. Mostly it is because I do a lot of camping, and ordinary shoes have a lot of drawbacks for this type of lifestyle. For one thing, I tend to rot my feet out each summer. Shoes are like incubators, holding in the dirt and sweat at warm temperatures, and culturing all kinds of fungus and bacteria. Walking through a little bit of water once or twice a day just compounds the problem, making it nearly impossible to dry out the shoes. My feet even rot when I take care of them, washing and drying my crusty socks each day.

While I am at it, I have other complaints too. You see, I do a lot of primitive camping, building my own shelters, starting fires without matches, gathering wild foods--that sort of thing. To me this type of camping is a way of getting close to nature by participating in nature, instead of merely camping in it. I like to touch nature, and I feel so removed in a pair of ordinary shoes.

I go barefoot as much as I can, but like most people, I have tender feet--because I don't go bare foot all the time. Moccasins are ideal for camping--at least to a point. I can really feel the earth through them, and it has a profound psychological effect on me, making me feel so much more in tune with my surroundings. The trouble with moccasins is they wear out--fast. It takes me about eight hours of physical labor to tan a deer hide, several more hours to stitch a pair of moccasins, and generally one or two days of hiking to wear the first hole in them. The holes always start at the toughest points on your foot, so they are not initially a

problem. You can get several more days of hiking in before you have to stitch in a new sole. Still, that is not a very long time at all. I have heard that some Native Americans carried multiple pairs of moccasins on journeys and spent each evening around the campfire fixing them.

I may practice primitive camping, but I also have to face the modern realities of the clock. My camping trips are typically short and full. I always have a lot of things I want to do while I am out. Fixing my moccasins every day is not one of them.

To solve that problem, I have tried over the years many marriages between buckskin and rubber to make lasting soles on my moccasins. The "paint-on" sole, a mixture of ground up tires and Barge Cement glue, does not work all that well. It helps, but even that wears through quite quickly under harsh conditions, and the rubber coating makes it difficult to dry out the leather of the moccasins. More so, they are not very patchable once a hole gets started.

I have also tried working with the "crepe soles", a thick sheet of rubber cement that you can buy, cut, and glue to the bottoms of shoes. The problem I had with these is that my foot no longer stayed in the right place on my moccasins. My foot was always sliding off the back edge of the sole.

After all these life-long problems with shoes, I was ecstatic to learn of something that actually did work. My friend Jack Fee and I were preparing to go out on a three-week expedition in the mountains. He made a new backpack for the trip, and I made some new moccasins. The best idea I had left to try for protecting the soles was a mixture of pine pitch, charcoal, and dried manure. I figured I could easily dope a little fresh material on the soles each night at camp to keep them from wearing out. I thought I was on to something, and the finished sole even looked good. Unfortunately, I wore completely through the pitch in two short city blocks, on a test run. I was out of a plan before we had even begun our expedition.

Jack then told me a story about Indians from Mexico coming to the United States and winning foot races in shoes cut from tires. I've been interested in using tire soles before, but it seemed like I would have to glue or stitch the tire to the moccasins. I had reason to doubt that it would work. I also once had a pair of tire sandals, made in Mexico, where the leather lacing was nailed to the tire soles. Those came apart within a couple of days.

Jack had never seen the tire sandals that were reportedly used by the Mexican Indians, but decided to see what he could do anyway. I have to say I was quite impressed with the final product, a sort of Teva-style sandal.

I was most impressed with the fact that there was no glue, and no stitching or strapping on the bottom of the sole where they would be exposed to the ground. Instead he cut the sole with some side tabs out of the tire as one contiguous piece. The first model was a little crude in appearance, but was amazingly comfortable. I too had to make a pair for the expedition.

The field tests of our shoes were quite exciting. The tire shoe and moccasin combination meant we had "modular" shoes. We wore both the moccasins and the soles when hiking, and then just one or the other around camp. We could use just the moccasins for stalking, or just the tires for walking in water. We climbed 10,000 foot peaks twice and really just put

on the miles. I did not wear socks, and never washed my moccasins, but my feet were in healthy condition for the duration of the trip—a first for me!

We did find that we would get blisters if we wore just the tires for any significant hiking, but we seemed to have no problems when the tires were worn in combination with moccasins, or with a couple pairs of heavy socks. I was amazed at how comfortable these shoes were, particularly because I once wore conventional hiking boots on a 500 mile walk across Montana, with severe blistering for the first 250 miles of the trip. Our new type of footwear gave me a freedom and comfort I had been searching for for a decade.

Our prototype shoes were crude, but effective. Since then, I have developed the idea some more, into the tire shoes shown in these pictures. The most significant modification was the addition of the tab at the very back of the shoes. That tab is not necessary, except in water. Without it your feet tend to slide forward off the front of the soles when the tires are wet. That back tab holds your foot securely in place. I also added the rubber buckles, and did away with the rope and buckskin ties of our early models.

Also for our prototypes we just traced around a pair of conventional Texas onto a tire, and started from there. I have since developed a system for creating a pattern to match your own foot. Plan on spending most of an entire day making your first pair. You will get faster as you make more.

#### Making Your Tire Shoes

First, place either foot in the center of a large piece of paper, at least an 8 1/2 x 14. Trace around your foot, being careful at all times to keep the pencil straight up and down. Next make a mark on each side, directly down from the point on your ankles (A) (see pattern). Also make a mark at the point along the inside of your foot, directly back from your big toe (B).

Remove your foot from the pattern. Now sketch a bigger outline around the tracing of your foot. Add about 3/8 inch for the toes and sides, but not to the back. Then use a ruler and bisect the pattern lengthwise, extending the line three inches past the heel. This serves as a guide to help you sketch the rear tab accurately. Now connect the marks you made by your ankles (A), extending a line three inches beyond each side of the pattern. These tabs will be sketched in front of this line. Also draw a line for the front tabs, extending from the single mark (B) across the pattern, perpendicular to the line that bisects the foot lengthwise.

The positioning of all these tabs is quite variable, and you can choose to move them forward or back, or at angles to one another, and all usually work, although the arrangement I have suggested may work more consistently. Problems usually arise with the front set of tabs. When at angles across the pattern they can twist a little and dig into your foot. If the tabs are moved forward or back then the edges can dig into that point (B) on the inside of your foot. That point is more pronounced on some people's feet than on others.

Now sketch in the five tabs, as shown on the pattern. These tabs are sized width-wise for 3/4 inch wide strapping, and should be made according to the approximate dimensions I've written in on the pattern, regardless of how big or small the foot. If anything you might make some adjustments length-wise, adjusting for particularly large or small feet. Finally, sketch in the holes that you will cut out to thread the strapping

through. This just helps you remember to cut them the right direction when you get to that stage. Cut the pattern out, and it can be used for both shoes, assuming your feet are fairly similar to one another.

As for tires, I would recommend truck tires, rather than car tires. The "corner" of any tire, where the sidewalls and tread come together, is always much thicker than the rest. You can work with that thickness in the tabs of the shoes, but not in the sole itself. Pickup tires are typically wide enough to work with, and you can make about three pair of shoes from one tire.

Most importantly, always use tires that do not have steel cables running through them. All tires have some kind of fibrous reinforcement in them, typically nylon or rayon threads. Most of the newer tires also have a layer of steel cables, which is not workable at all. Still, there are a few billion of the older tires around without steel cables, so you should not have to look too far to find some. Just look on the sidewalls of the tire and it will be printed there how many plies of nylon, rayon, or steel are imbedded in the rubber.

We used simple utility knives to cut out our first shoes. Doing it this way you can trace around the pattern on the outside of the tire and start cutting. However, I must say this is very laborious and not much fun. It is hard work, and you could easily slip and cut yourself with the utility knife. Along the way I have discovered that it is much easier and more enjoyable to cut tires using sharp wood chisels or a bandsaw.

To do the chisel or bandsaw method you must first remove a section of tire. This allows you to run the piece through the bandsaw, or to put it on a wooden block, where you can chisel from the inside out.

A circular saw works fairly well for cutting tires, except that it creates a lot of blue-black smoke, and binds frequently. Cut out a piece that is at least a half inch longer than your pattern, and save as much of the sidewalls as you reasonably can. These are useful later for making the buckles. Do not try cutting through the inner edge of the tire, which has an imbedded steel band to fit the tire snug against the rim.

Now, trace the pattern on the inside of the tire, being certain that the pattern is centered and straight on the tire. Even a slight 1/2 inch angle along the length of a shoe can cause problems when you wear it.

I've done separate tests, cutting out the shoes with chisels and with a bandsaw, and the bandsaw method is only a little faster. A good set of wood chisels works just fine if you do not have the bandsaw.

I would suggest making only one shoe at a time, and completing it. Finish the one and try it on; you might think of some modifications to improve the next one. Few of my pairs of shoes are exactly identical, as I usually find some new idea to try on that second shoe.

The next step, after cutting out the shoe, is to thin the four side tabs. The tabs are generally cut from that "corner" on the tire, where there is a thick lump of tread. These are easiest to thin on a bandsaw. You can, however, do a crude but adequate job by cutting the lump down with some careful chiseling or with a sharp knife. Thin down as close as you can to the nylon/rayon plies, without actually cutting any of them. This step is not easy by any method I have found, and I typically leave 1/8 to 1/4 inch of rubber covering the plies, for a total thickness of up to half an inch. That is still quite thick, but thin enough to work.

Now, to make the tabs flex upward, take a razor blade and slice straight into the tread of the tire at the joint where the tab attaches. Slice in all the way until the plies inside are exposed. Be careful not to cut into those fibers.

Chisel out each of the eyelets, where the strapping will be threaded through. For this I use a 1 inch chisel and a 1/4 inch chisel. Be careful to not cut too close to the edge. If you break out the side of a tab, then you generally have to start all over. Also cut a set of buckles from the sidewalls of the tire. These are easy to do.

For strapping, I use a sort of a nylon harness strapping, available at farm and ranch supply stores. 3/4 inch wide strapping works well with the one inch slots. Cut pieces that are extra long, you can trim them off after you thread them through. Use a match, and melt the end of the nylon strap to secure the threads. To do the back strap, thread through the hole marked point (C) on the pattern and stitch an inch or so of the strap back on itself. Thread around through the other eyelets, through the buckle, through the other hole on the first tab, and once again through the buckle. The front strap should be threaded through the buckle, through both eyelets, and back through the buckle again. This system is a little hard to adjust, but once set, I find I can slip my foot in and out, without having to tighten or loosen them.

The finished shoes should be comfortable to wear, although you may need to do some fine-tuning to get them right. For any serious hiking you should wear a couple heavy pairs of socks, or moccasins, or bring along some moleskin.

To follow up with Greg's worry about the fish bombing thread, I would like to address the issue of environmental ethics which has also been aired by a couple of others since that subject has been discussed.

Please note that one of the purposes of this group is to conduct research on wilderness survival techniques, and obviously any of the primitive techniques relative to the taking of animals are highly illegal and often ecologically disastrous. We all know this! At the same time, it is these very techniques that are some of the most important to know in case of natural disasters or real survival situations where you must obtain food to survive. These subjects also have historical significance, and as such merit to be studied.

I say that knowledge of any of these techniques does not at all mean that people are going to use them. After reading some of the torture stories of the Iroquois prisoners, one does not go out and try them on their neighbors. I have no intention of going to blow up fish just because I now know how. However, Alcan aluminium has horrible lakes of toxic wastes which are all red in color a few miles south of Chicoutimi,

where they have been dropping their mess for the last dozens of years. I just might obtain permission and go and try a few bombs there!

Another example: I learnt lockpicking many years ago and could now walk into most peoples homes just as fast as if I had their key. That doesn't mean I'm going to go and steal TV sets over the weekend! But how many times has that knowlege saved me and others who had misplaced keys...

Here in QuÈbec a bunch of 90 poachers were apprehended this last fall. They were taking moose illegally with all kinds of ingenious traps and snares of their own design. These guys obtain their information from various places, but mostly from their own underground sources. Knowledge of their ways will not turn an honest citizen to a poacher. But it may give you food in an emergency.

My point is that bad guys will be bad guys, and will get their info somehow no matter what. No amount of knowledge of bad ways will turn a good guy bad.

The purpose of our group is not to feed info to bad guys. We are all here because of our desire for learning and sharing primitive skills, and some of these skills are definitely out of line for realistic use outside an emergency. That doesn't mean we should not discuss them here.

Last month I caught 7 mice at the cottage with a figure 4 deadfall made from 3 pieces of firewood and a cookbook. Nobody's going to beat me up for doing that, and it helps me learn details of trapping. There are always honest ways to practice primitive skills.

All this to say that I think that poaching ways and fish bombing can be discussed freely in this group. To me these should not be taboo subjects. As long as subjects concerning the taking of animals continue to be treated in the same respectful way it has been thusfar (information regarding techniques), I do not have any problem whatsoever.

At the same time, I agree wholeheartedly with the essence of Greg's concerns. I too would be concerned with statements of joy and pleasure regarding bunny bashing and blowing fish guts to smithereens. I don't think any of us here are stupid enough to crawl that low, and I'm sure that if ever anyone would try that kind of behavior, they would be strongly reprimanded by the rest of the group.

Thank you everyone for reading this and feel free to respond if you wish. Just trying the best I can to provide a possible orientation on this difficult topic.

Sincerely,

AndrÈ

I think that there are many people who have incidental experience with the methods described. My father, a forester, mentioned incidents he had experienced or his friends had experienced in the course of their duties.

This would provide me with information albeit 2nd hand, that is reliable and reportable, but, I didn't have to break any laws or abuse the environment to acquire the knowledge. I just can't see any harm in passing along that knowledge and in fact I think that it is good that we understand the results because we can identify such activity when we see the effects of it which, otherwise, we might not recognize.

I do not support poaching or abuse of the environment, but, I also do not support the PETA or Earth First approach.

Neal, ME TOO!!! :) :) Don't apologise for this thread, it's a great one.  
 I agree with you and others that these methods shouldn't be used outside of  
 an emergency situation. And then should only be used with groups or extreme  
 conditions. Someone mentioned the responsibility that we all have to the  
 earth and its people (critters too!) there's a word for what we should be  
 doing. It's "Husbandry!"

I don't agree with extremeists on either side. All too often I've seen  
 statements that would reflect little or no knowlege of the topic expressed.  
 Sure, lets save all the cougars, until someone in Marin county runs between  
 a mama cougar and her kits and gets mauled. Then we go on a cougar hunt  
 that kills mama and starves the kits.

Ok I'll get off my soapbox now as it's off topic and boring! What you need  
 to know is that I enjoy hearing from people, even those as contrary as you!  
 :) :) :)

Merv

There have been no problems with advertising on this list since it has started, but in order to prevent future concerns, here are some guidelines which I may suggest:

1. Unsolicited advertising of any kind by non-members will be severely frowned upon.
2. Unsolicited advertising of a service or product by members which is DIRECTLY RELATED to primitive skills may be acceptable as long as it is sent ONLY ONCE and for informational purposes only.
3. In direct answer to a question, reference to commercial sources of information, services or products is OK.
4. Personal opinion or judgment of members on a particular commercial product or service is much preferred to sending advertisement on same.

Hope this helps orient future postings, and thank you for reading. If you have comments about this, please respond.

Thanks for posting this. I've had some concerns about the  
advertisements I've seen. I now understand the groups guidelines, and  
will be more tolerant of those posts. If these guidelines were  
prompted by my complaint to the author of the "updated boomerang  
software" post, please understand that we have come to a mutual  
understanding and have cleared the air regarding my interpretation of  
his posting. I'm not used to seeing a list that tolerates advertising  
however your guidelines, if abided by, are very reasonable and fair.  
Thanks again.

Hi everyone, please read this post!

I have been very carefully monitoring the Tom Brown discussions and have learned a great deal about the nature of the controversy surrounding this colorful individual. I thank each and every one of you for holding back your flames as much as you did, and for respecting the group guidelines as much as you possibly could under the circumstances. I also thank all of those who acted on behalf of the group to suggest a re-focus of the discussions towards primitive skills subjects.

You certainly noticed that I did not intervene during the Tom Brown discussions. I want all of you to know that I WILL NOT ACT AS POLICE for this list. I want this group to be as much yours as mine, and I would like it very much if everyone could participate in it's orientation.

However, several of you noted your desire for me to intervene somehow, and in reaction to that wish, and simply in an effort to keep the group focused, I have written the following guidelines which I intend to post every couple of weeks for the benefit of new members. I also intend to

include these guidelines as part of the "Welcome message" new members get when they first join the list.

I WANT YOU TO CRITICIZE these guidelines now, if you wish, before I post them repeatedly. I consider that these guidelines reflect the thoughts of all of us who were around when we first started this list, and also reflect the thoughts of those of you who have recently transmitted your ideas on group orientation.

Please, if at all possible, take the time to read the guidelines carefully and send your comments if all is not to your liking.

Many thanks to everyone for sharing their incredible knowledge. Personally, I am very proud of the quality of this group, and I'm sure you will all agree that it is a very worthwhile venture.

Keep up the good work, and thanks for reading this.

Andr -Fran ois

-----  
PRIMITIVE SKILLS GROUP GUIDELINES  
=====

ALL NEW MEMBERS ARE ASKED TO READ THE FOLLOWING GUIDELINES CAREFULLY.

To communicate with the group, send an E-mail with your message or question to:

Primitive-Skills-Group@uqac.quebec.ca

PURPOSE OF THE GROUP  
-----

The main purpose of this group is to provide a way by which all lovers of primitive skills can discuss various subjects related to wilderness ways.

TOPICS TO BE DISCUSSED  
-----

Topics which you are ENCOURAGED to discuss with other group members are:

1. All primitive wilderness living skills such as shelter, fire, cordage, primitive tanning, natural foods, primitive living, primitive rafts & boats, primitive direction finding, primitive trapping techniques, weapons for wilderness survival, primitive hygiene, protection from insects, primitive weather prediction, fighting cold, primitive medicine, traditional dog sledding etc.

2. Subjects related to modern realistic wilderness survival, such as surviving when lost in the wilderness, or surviving unexpected emergencies after airplane crashes, broken down snowmobiles etc., are also welcome.

Please note:

Discussions should be restricted to PRIMITIVE SKILLS only.

By SKILLS discussion, we mean sharing "How-to" information which help group members learn how to accomplish a particular physical task which is useful in a wilderness setting.

By PRIMITIVE discussion, we mean sharing info on skills which are possible in the short term using only materials found in nature, or at least available in the average recreational hiker's backpack.

Topics which you are DISCOURAGED from discussing with other group members are:

1. Topics dealing with religious, spiritual, or belief-based concerns. For example, we do NOT wish to discuss subjects dealing with dousing, natural apparitions, psychology, philosophy, gurus, prophets, spiritual leaders, or the particular styles or approaches of any particular survival expert.
2. Topics dealing with warfare or survival after man-made disasters. For example, we do NOT wish to discuss subjects dealing with explosives, survival fighting, nuclear war preparedness, and so on.
3. Topics dealing with political or environmental issues. For example, we do NOT wish to discuss subjects dealing with whether it is right or wrong to kill animals, or whether a wilderness area should be protected, and so on.

All members are asked to help "enforce" the above guidelines with regards to topics of discussion.

#### ADVERTISING

-----

1. Unsolicited advertising of any kind by non-members will be severely frowned upon by all group members.
2. Unsolicited advertising of a service or product by members which is DIRECTLY RELATED to primitive skills may be acceptable as long as it is sent ONCE ONLY and for informational purposes only.
3. In direct answer to a question, reference to commercial sources of information, services or products is OK.
4. Personal opinion or judgment of members on a particular commercial product or service is much preferred to sending advertisement on same.

#### GROUP NETIQUETTE

-----

This is a high volume list, and current group members have asked that the following etiquette guidelines be followed whenever possible:

1. Please always rename subject headers when replying so that the header always matches the content of the message (helps store archives).
2. Please stick to one subject per message (helps store archives).
3. Please send "I agree with you", "Thank you", and "Bravo" messages

which have no actual content through private E-mail (these are important, but clutter the list too much).

4. When replying, please quote only the passage which permits to follow the discussion, not the entire previous message (facilitates reading replies).

5. Note that there are two Reply-to addresses when you send a reply. One for the group, and one for the sender. Please delete one of the two (so the sender doesn't receive double messages).

6. Please keep signature files as small as possible (4-5 lines).

7. Please read at least the primitive-skills archive headers so you don't ask a question which has already been answered.

8. Please read the list-of-introductions archive so you have an idea of who's who in the group.

9. Please avoid sending "funnies only" messages to the group. We all appreciate a good joke, and even more so when it is part of a message which has content too (prevents list clutter).

#### COMMANDS

-----

The following commands are available by sending an E-mail message to:

[listserv@uqac.quebec.ca](mailto:listserv@uqac.quebec.ca)

SUBSCRIBE Primitive-Skills-Group (subscribe to the mailing list)  
SIGNOFF Primitive-Skills-Group (remove yourself from the mailing list)  
REVIEW Primitive-Skills-Group (get a list of subscribers)  
QUERY Primitive-Skills-Group (get the status of your list entry)  
SET Primitive-Skills-Group NOMAIL (remain listed but receive no mail)  
SET Primitive-Skills-Group MAIL (to reverse the NOMAIL setting)  
SET Primitive-Skills-Group NOREPRO (prevent sending you your own posts)  
SET Primitive-Skills-Group REPRO (to reverse the NOREPRO setting)  
HELP (to receive this help file)

Put the command in the body of the E-mail (nothing else). The subject header will be disregarded.

#### UNSUBSCRIBING

-----

Please save the following information!

To unsubscribe, you must send an E-mail with the following command in the body of the message (nothing else):

SIGNOFF Primitive-Skills-Group

The header will be ignored. Send the message to this address (NOT to the group):

[listserv@uqac.quebec.ca](mailto:listserv@uqac.quebec.ca)

I'd just like to throw in my \$.02 that it seems odd to worry about "policing" the list. Although there was talk of flames going back and forth, I don't think anyone actively involved with the discussion felt flamed. I've only seen one flame on any list I've been on, and it looked a whole lot different than our "heated discussion." A flame goes more like this: Why, you #\$\$%Q#&\*\$(&!!!

I thought the discussion that brought all this up was interesting, and I hated to see it go underground into the land of private e-mails. If a discussion takes on life, it ought to be allowed to live -- to be born, learn and grow, and then die a natural death. No cops, no capital punishment. I think everybody on the list is capable of hitting the "flush" button on anything they're not interested in.

Aloha,

--John

I approve of this philosophy; moderated groups are much to slow for good exchange of information and opinion. What you might consider is to privately point out to anyone who severely breaches the guidelines that he or she might want to reconsider continuing the topic or please refrain from doing so again. Your word as listowner does carry a bit more weight.

This is when the archive comes up? You should the include some information on how to access the archive. Is it on WWW or by mail?

> SIGNOFF Primitive-Skills-Group (remove yourself from the mailing list)

In order to (a) get it done, and (b) save the poor lost soul the embaressment of being instructed in basics in public you might want to include a sentence somewhere that you will personally send instructions to those who send "unsubscribe" to the list, and noone else needs to do anything about them.

>TOPICS TO BE DISCUSSED

>-----

-----snip-----

"Topics dealing with special needs involved with survival after man-made  
disasters excluding subjects dealing with explosives, survival fighting,  
nuclear war preparedness, and so on."

This is the only topic that I can think of that your guidelines don't allow  
for. I believe it shouldn't be shut out of this list. There's special  
rules after a nuclear incident and most likely they would have to be  
followed in a primitive manner. I'm not interested in how to fight, etc.,  
but am interested in how to find safe water.

I'd imagine there's knowlege on this list that would help me. If you don't

want it in open discussion, I'd be glad to entertain private email, as I said, I am interested in this. If it works for a nuclear incident, it'll work for other "problems" too.

-----snip-----

>Topics which you are DISCOURAGED from discussing with other group  
>members are:

-----snip-----

2. Topics dealing with warfare.

This adaption would cut one of the disallowed topics to the above.

Thanks Andre. This set of guidelines is Great!!!

Last Saturday Ben Pressley of Tribe conducted a day-long seminar on construction of atlats of the type used by the Native Americans indigenous to North Carolina. The workshop was held about 20 miles from my hometown of Gastonia, North Carolina but I would never have heard about it had it not been for the Primitive Technologies page maintained by Thrower list member Ted Bailey. Ted's Primitive Technologies page, which contains information on other upcoming Tribe workshops, may be found at <http://ic.net/~tbailey/Primitive.html>

The instructors, wearing homemade buckskin shirts, were Ben Pressley and Robert Didn't Catch The Last Name. Of the three students making atlats that day, two of us found out about the seminar via the Internet, myself and Matt, a college student from Virginia who came down for the seminar with his girlfriend Rayna. The other student was Sam, a fellow who had attended several previous primitive technologies seminars with Mr. Pressley.

We spent the morning shaping our atlats out of pieces of seasoned bow wood. My choice was osage. Using machete, cane knife and bowie knife, we set upon the chunks of wood with various levels of woodworking skill. We were making authentic atlats of the Basketmaker Period with integral hooks. After lunch, we began on the darts. First fire-straightening lengths of bamboo or more authentic rivercane, then whittling hardwood foreshafts with firehardened points. We fletched with turkey feathers, using sinew, dogbane cordage or (my choice) synthetic sinew to attach the feathers to the dart. The cordage was

glued with a mixture of pine pitch and charcoal from our fire with hardened to a glassy finish similar to jet.

Leather finger loops completed the atlatls and we were ready for the most exciting phase, casting them. First, we were encouraged to throw the darts by hand. The results were dismal; we were no threat to the local fauna. Then we tried the atlatls. I'm a poor judge of distance but if my first cast didn't go 100 yards, I'll eat my dart feathers first! Ben and Robert cast their darts nearly twice that far without seeming to expend any effort at all.

I asked Ben about the Sling and Bola workshop scheduled for the 16th. He said that it had been cancelled due to lack of interest but he happened to have a couple of slings with him and offered to give me some pointers. The first thing I noticed about his slings was that he didn't use a finger loop on the anchor line. Instead, the line passed through a hole in the center of a one inch square plaque of slate on which he had carved an indian design. When I commented on the carving he said that there weren't many ways to decorate a sling. He was obviously a believer in the Church of the Decorated Weapon. The next thing I noticed that all but one of the slings that he and Robert used were the same length; with both cords held in the throwing hand held out to the side of the body, the pouch came to the center of the chest.

I was most surprised, however, by their technique. Ben suggested that I twirl the sling in a horizontal plane over my head, like a lasso. I was skeptical, having tried this before and having no accuracy at all. But he went on to say that when you were ready to fire, you accelerate the sling for one fast turn and when the stone is behind you, change to an overhand throwing motion. Now I was really skeptical -- changing motions in the middle of the throw? But I tried it and nearly fainted at the result. That was the best sling throw I had made in my life. The stone went straight where I aimed it and faster than I had ever made my wildest pitch.

Then out came the big gun. Robert pulled out his mega-sling. Holding the cords in his hand straight out in front of him, the pouch came down to his ankles. He put in a large stone and walked several yards away from our group. He began swinging the sling in slow lazy circles, vertical, horizontal, diagonal, changing from one side of his body to the other while moving around in a manner which reminded me of stylists of Tai Chi Chuan. After this meditative warm-up, he brought the sling overhead, picked a target and let fly with the overhand throwing motion that Ben had taught to me. I didn't believe what happened next, even as I saw it. The sling whooshed through the air, making a noise like a whip. The stone shot out of the pouch too fast to follow with the eye, making a high-pitched buzz which faded quickly into the distance. About a full second

later there was a sound like a pistol shot from deep in the woods across the train tracks as the stone encountered a tree. Every tall tale I've heard about slings I now believe. Goliath never stood a chance against David. Alexander's men could easily have bombarded the enemy from 500 yards away. I wouldn't go against Robert with a rifle if he had that sling in his hand.

I asked Robert and Ben if they knew about the Andean braided slings. Robert opened his pouch and pulled out about a half-dozen slings of various designs and materials, finally coming across his alpaca-hair braided sling. It was as soft as rabbit fur and the split pouch was large enough to accomodate a baseball. Now I *\*have\** to order that book. Anybody know where I can get some alpaca hair?

As well as materials and instruction for making our own atlatls and darts, we were also given a class handout. Forty-four pages long, it contains detailed instructions for making the type of atlatl and dart we made at the workshop, popular and scholarly articles on many varieties of atlatl from around the world, and on the types and purpose of bannerstones. There is also an article on thong-thrown arrows from which I must quote the following:

...Gallwey repots distance of up to 372 yards!

To put this in perspective, a 70lb bow is about the comfortable draw-weight limit for a typical archer. Such a bow can be expected to cast a normal weight hunting arrow about 250 yards...But 370 yards! And by hand?!

Gallwey had to be wrong. And there was a simple way to prove it. [...]

The arrow was thrown toward a pile of hay at the end of my driveway. Then two unexpected things happened: 1. a surprisingly heavy tug as the arrow was released... 2. the arrow disappeared.

Then there was silence in the neighborhood. A long uncomfortable silence, followed in time by the distant but unmistakable sound of a 125-grain steel field point imbedding in wood siding. Gallwey was on to something.

The handout is filled with photographs, diagrams and drawings. You could easily reverse-engineer about a dozen different types of atlatl and darts from the information contained within. It has discussion of materials, construction techniques, tips for correct throwing and trouble-shooting advice. The physics as well as the history of this venerable weapon are discussed. I asked Mr. Pressley if he would mind if I distributed copies of the handout to members of the Thrower list, asking only to be reimbursed for my costs for copying and postage. He readily agreed.

Instead of a group order for atlatls, the plan has changed. Please let me know if you would be interested in having a copy of this handout. The copies will cost me \$2.20 per handout.

I'll run by the store and the post office in the afternoon to see how much the envelopes and postage will cost but we're probably looking at under \$5 if you are within the States.

Touch of the Bear. Already into cord wrapping and braiding (whip interests). I wonder if you've read this article yet ("A Rock For A Rock"):

[http://www.ucalgary.ca/~elsegal/Shokel/880527\\_Rock4Rock.html](http://www.ucalgary.ca/~elsegal/Shokel/880527_Rock4Rock.html)

Thanks James (from an NICU RT). Taken my whips and knives indoor for the season, so I need the project material.

With all the interest in Ben Pressley's atl atl workshop handout, many of  
you may have an interest in finding out more about Ben Pressley's Tribe  
organization. The WWW Page for Tribe is:  
<http://users.aol.com/tbprim1/Tribe.html>

Tribe has a rather nice newsletter at a really good price. the group holds  
a primitive technology gathering in the Spring or early Summer, each year.  
If you want to find out more, there is a link to Ben's email address on his  
WWW Page. - Ted

Thrower Marlo Brown's 4-strand macramed rope whip construction article was an original work for Thrower list subscribers and resides on Thrower's whip page:

<http://www.crl.com/~mjr/whip.refs.html>

A number of Thrower contributions throughout it's website have been noteworthy enough for other sites to co-opt them, sometimes without attribution.

"Imitation is the sincerest form of flattery."

Andre;

I've read about various toxins used by aboriginal peoples for various purposes, such as the strychnos toxifera plant that is the source for curare, and using certain plants as fish toxins in fairly sluggish pools of water( i beleive it was walnut hulls), but as for having actual experience in using them I have to say no. If I were to use a poison for hunting larger game I would probably turn to the most readily available vegetable toxins or nicotine sulfate from a concentrated tobacco slurry. Nicotine attacks the nervous system of the animal and would cause death after a short time from a fairly minor wound. I would have to really work on my tracking skills though. I would also cut out the meat immediatly around the dart wound to reduce the amount of toxin ingested

In Panama, we have many species of small brightly colored flogs called:  
"Dedrobates" (sp?). They are also called "Poison Arrow Frogs" They exude  
toxins from their skin when they get upset. You can play with them in  
your hands if you do not crush them or eat them. The natives put them on a  
hot stone to make them mad, then, they rub their darts on the skin to make  
really potent darts.

The natives in Panama also boil a vine that grows at the edge of the rivers  
and dump the "tea" into a slow stream. For some reason, the "tea" is a  
toxin that prevents the fish from getting oxygen to their gills and they  
float belly up. I found that M-80s and hand grenades were more effective  
means to catch fish and were probably more environmentally friendly as well.

Just a reminder to those who get this in time. Today (Dec. 29, 1999) on the Discovery Channel are two programs dealing with traditional cultures in the rainforest of South America. There is discussion of blowguns, poisons for the darts, edible and medicinal plants, and other topics some on this list will find interesting.

Good Luck (or is it good blessings),  
Jim W.

To continue the discussion from the thrower list, I've used blowguns for some time. My favorite blowgun is a short 4 feet long and .625 interior diameter. After reading Laubin's book and reading a few other sources I tried to recreate the Cherokee darts. I don't quite have the wind to send a two foot dart enough distance to be useful, but a 10 to 12 inch dart works out just fine. I also like paper cones as a bore seal. Mostly, other than target work< I have little use for the sharp darts, I do use stun darts to chase cats in heat from beneath my window, and stray dogs from my yard.

The .625 blowgun is sold by J.W. Mcfarlin Co.;P.O.Box 209; Lake Havasu City, Az 96405-0209. It is supplied with nail and fairly thick wire darts with plastic cones and injection molded stun darts that work very well to chase pests and can be very enteresting for games of bug tag. They hit hard enough to create an inch wide welt, or stun/kill birds up to the size of a starling.For those not of the techno-primitive bent it would be fairly easy to cobble up darts of dogwood shoots,dowling, or splits from suitable wood(with a froe or other similar tool) Birchbark would indeed make an adequate replacement for paper with pitch for glue. Still if I were to turn to gathered materials, I would probably make them much asthe Cherokee,and Creek indians did with thistle down tied on with sinew or fiber cordage. If you are lucky enough to live in the Southeast there is river cane. Elsewhere you might turn to a straight sapling of another type of about one

inch or so in diameter at its narrowest point. With the cane you bore your way through or grave and split then scrape out the sections, and then glue and bind together. With the sapling you will have to split lengthwise through the center and then scrape out your channel through the center in whatever diameter you want. I would advise about .50 inch inner diameter or perhaps slightly bigger.

I have no local sources of cane, and so rely on neo-primitive sources such as the hardware shop for sources of hard copper, steel, or aluminum tubing. For a mouthpiece I use either cane tips or stool legg tips and hot glue them into place. I rely on dowling or bamboo skewers in about 1/8 inch in diameter and either tied on cotton or acrylic yarn to fletch the dart. The tips are scraped to a point, and will penetrate card board or other fairly soft targets.

My sources of information for my blowgun studies are

A SPORTING CHANCE by Daniel P Mannix (1967)

AMERICAN INDIAN ARCHERY by Reginald and Gladys Laubin(1980)

AIRGUN DIGEST both the first and second editons

WOODSMOKE compiled by Richard and Linda Jamison(1994) has an article by Steve Watts titled "The Ultimate Weapon-The Southeastern Indian Rivercane Blowgun" They also have an article on the fire piston.

BLOWGUNS THE BREATH OF DEATH by Michael D. Janich(1993 Paladin press) with a dramatic title but actually has a pretty solid description for the neo-primitive that wants to make a blowgun.

I've seen Laubin's book at local bookstores as a new release paper back.

Neo-primitive is my own label for people using primitive techniques today but not necessarily with traditional materials.

Re-sending for Andr ,

A short passage on Amazon blowgun construction from a travel diary-like book by a college professor from Ohio ("Don't Drink The Water," by Ida May Sonntag - 1980). She details her experiences during vacations and sabattical leaves:

"The people along the river are largely of Indian descent. I was able to barter for a Zarabatana (blowgun) with a member of the Maku tribe. This weapon is a simple yet precise hunting instrument. Only small game is hunted and contrary to popular belief is not used for warfare. The shaft is made of pachuiba (palmwood) while the mouthpiece is made of Brazilwood attached with a tree resin. Dart cases are made of woven palm strips and the darts are made of palmwood with wild kapok cotton stabilizers. With practice the Indians can hit small birds at 100 ft."

Note: The site, about 11 mi. from the Amazon, along the Rio Negro river, near Manaus, Brazil. From the books cover jacket photo: Three Indians wearing long red-orange and yellow feathered headdresses. A man and boy shoot at some target with their blowguns, while a second man sits with his blowgun over his shoulder, watching them and the photographer. The blowguns are blackened, of large caliber and appear to be approx. 6-7 feet in length. Each has a cylindrical woven dart case, appearing much like an archers quiver and hung around each's neck by a tripled section of medium weight cordage. The dart cases hang down in front to their waists. The darts are approx. 18-24 inches in length and are about as thick as pencils. The darts extend above the top of their cases about half their length exposed. Each appear to have about 10 or 12 darts. They are gathered in a rain forest village in a forest clearing with a thatched open air long-hut (with hammocks hung inside) behind them, next to a stand of banana trees.

Last time I was in Costa Rica doing research, an old Indian from Tortueguero village  
showed me that same frog, and told me about the poison. Very potent apparently.

Glad

to know this extra information, thanks Ted.

I know that the common northern toad, Bufo americanus, also has poison glands on it's  
back, although much less toxic. Does anyone know about this poison and how potent it  
is? I don't think it's strong enough for blowdarts, but I would like this confirmed.

Harmon Seaver said  
>You have to use poison, that's what the indigs use.  
>

Not true, The South American Indians used a combination of poisons with the main ingrediand being curare. The natives of Southeast Asia, like the Dayaks used Antarias toxicara or Strychnos tieute. The Cherokee and the other peoples of North America that used blowguns used no poison on their darts relying instead on penetration and shock, or at least there is no recorded information of poison use on blowgun darts. Poisons have been used on arrows for warfare as recorded by Laubin and mainly consist of snake venom in putrid meat. Since their recorded use was for small game, there was no need for poisons on blowgundarts in N.Am. Also there are few plants that such venoms can be extracted. I suppose nicotine poisons could have been extracted from tobacco and milkweed, but I've not seen any recorded proof. The few Cherokee sources I've heard from say no such venoms were used or necessary.

>> Go to your friendly neighborhood hardware store and  
>> buy a 5 foot length of aluminum electrical conduit with an inner  
>> diameter of 3/4 inch (I use 1/2 inch and it works just fine.)

-----snip some great stuff!-----

That was one of my favourite diversions while on mid watches. You know, with a 1/2" piece of conduit 8 feet long, I can curl a seven inch piece of 10 guage copper wire into a tight spiral by blowing it into a piece of sheet steel!

The darts were made as above except for copper wire instead of steel. I did use a piece of tool steel once, just too damn dangerous for play. It penetrated 1/8" particle board backed by 1/16" copper, and travelled on into a 2x4 behind that. (The penetration depth was 3/8" with an 8' tube and 20' of flight beyond the tube.)

>> There's not much to technique, point and blow. One variation is

>> to push the dart a few inches into the tube, block the tube with  
>> your tongue and build up pressure by blowing with the tube blocked.

For the blow, it's almost a cough. Dump every bit of air on your lungs  
before the dart leaves the tube.

>>I would practice indoors by putting an empty coke can  
>> in one room of my apartment and shooting at it from another room,  
>> as far as I could get away from it in my small apartment.

Heh, use a warm full coke can...outside...much more satisfying. Fun to roll  
down the road and shoot on the roll too! I'd still use copper wire darts  
though as the steel just ricochets too good.

Happy Huffing

Merv

I have also made one shot darts with cotton balls by only licking the dart shaft and then wrapping the cotton around the dart shaft. Many types of wood slivers will work as darts. And if you have cordage, even lightweight cotton string, then there are many fletching materials you can use. I have used many plant fluffs, small bird feathers (fluffs or tiny feathers that have to be spiral tied in layering each row from the bottom up where they lay over each other tied at the top and loose and overlapping toward the bottom of the dart. My favorites are thistle down and turkey leg feathers.

I bought what I thought was an old South American blowgun two years ago. The blowgun was only 5 foot long and the central hole was quite large compared to other blowguns in my collection. It came with a beautiful primitive woven bag that was full of clay pellets about the size of a large pea. I guess the South American Indians must have shot and stunned small birds with the clay pellets to obtain feathers for their arrows, headress, etc.

That's true, I've done it with a plastic stun dart that is essentially a ball ended dart. It will knock a bird the size of a starling or Black bird out a tree, and stun it enough to allow you to pick it up. "four and twenty blackbirds singing in the pie"

>>Welp, the Latin American natives use curare (sp?) as a poison on their darts. I think that like boomerangs, blowguns have much too much fable attached to their effective uses. No, I'm not a user or expert with blowguns...but I do watch DISCOVERY and other such science TV shows.

Details fail me, but not too long ago, I watched S.American natives hunt tree monkeys, using bamboo material BGs. Length:perhaps 6 to 8 ft. Dia. might have been 3/4" ID. Darts were dipped in poison, that attacked the monkey's breathing muscles.

Native tracked animal as it swung thru trees, high above, and when the game stopped, hunter, pegged the bloke. I recall that the breath-power came from using the diaphragm to help propell the dart.

On this same show(or one very similar) natives would use a very long, thin blowgun, 12 or more feet long, and they would "snake" the BG thru the branches, getting right up to the bird they wish to kill, and then they pop the dart into the bird.

Finally, cure'(this spelled correctly?) was not used against humans as salt was the antidote, so very easy to thwart the effects...I read somewhere.

Looking forward to this new list. Thanks, Andre'.

I saw the same program. My understanding of why toxins are not used against men is because it's not done, bad juju, dishonorable. Pick one of the above. I use medications derived from curare fairly frequently and they are often given to people via Sterile saline (salt) I.V. drip. We wouldn't do that if slat deactivated it. Curare attacks the stuff that carries neural transmissions across synapses. Neural transmission is interrupted and the animal can't breathe. Works on men the same way it does animals, and get this, you are fully awake, and feel everything as you smother to death on your own weight. That's why we put people on ventilators and sedate them so they aren't terrified about their paralysis.

Andr ,

How's the blowgun working out? Careful about all those pins in the ceiling raining down on you, eh? . I've just read this not-to-well written travel diary as-a-book, by Ida May Sontag written in 1980 and called "Don't Drink The Water." I read it because the book jacket has 3 Amazonian Indians in loincloths and long ceremonial headdresses, puffing through very large blowguns (the look at least 6 ft. long), with hammocks inside an open air thatched roof long house near banana trees in the background. Not much on blowguns in the book actually (it's about her world travels during her teaching sabbaticals and holidays), but here's what she's written:

"The people along the River (my note: near Manaus, Brazil on the Rio Negro, 11 mi. from the Amazon) are largely of Indian descent. I was able to barter for a Zarabatana (blowgun) with a member of the Maku tribe. This weapon is a simple yet precise hunting instrument. Only small game is hunted and contrary to popular belief it is not used for warfare. The shaft is made of Pachuiba (palmwood) while the mouthpiece

is made of Brazilwood atatched with a tree resin. Dart cases are made of woven palm strips and the darts are made of palmwood with wild kapok cotton stabilizers. With practice the Indians can hit small birds at 100 ft."

I'm sure I can hit one of my dogs with a plastic stun dart (no needles) and my 2 ft. store bought "bacpacker's" blowgun, inside my living room (my wife would have a fit if I used the .40 cal paintballs).

Take it easy AndrÈ,

Best wishes,

Chris (in Coeur d'Alene, Idaho)

Depends on what you're hunting, doesn't it? I used mine to kill rats before the local McDonald's went out of business. One shot did the trick. Amazon indians poisoned their darts and one dart usually delivers enough of the toxin to make a monkey let go of his branch and make a rapid descent. I doubt anyone is going to hunt deer with a blowgun though.

OK, since blowguns have been ruled acceptable as a topic, here is my

blowgun recipe. Go to your friendly neighborhood hardware store and buy a 5 foot length of aluminum electrical conduit with an inner diameter of 3/4 inch (I use 1/2 inch and it works just fine.) File the ends smooth so you don't cut your mouth. A mouthpiece isn't necessary but feel free to improvise. For darts, I use music wire (thin steel rods) from the hobby shop, although finishing nails will work too. Cut 4 inch lengths and sharpen. For fletching, wrap a piece of paper into a 45 degree cone and tape. Stick the dart through the apex of the cone and tape in place so that the cone is at the back of the dart. Drop the dart point first into the tube and mark with a pencil where the tube meets the paper cone. Remove the dart and cut off the excess paper so that the dart just barely fills the tube. The paper fletching will tear apart after a few shots. Try using a disc or cone made of nylon or some other sturdy yet flexible material.

There's not much to technique, point and blow. One variation is to push the dart a few inches into the tube, block the tube with your tongue and build up pressure by blowing with the tube blocked. Use your chest muscles to pressurize the air in your lungs then quickly pull back your tongue, releasing the trapped air at once. I haven't had much luck with that technique. It causes a jump which spoils my aim although it does seem to increase power if you can manage to pull back your tongue quickly enough.

With little practice, you will be amazed at how accurate this primitive weapon is. I would practice indoors by putting an empty coke can in one room of my apartment and shooting at it from another room, as far as I could get away from it in my small apartment. I rarely missed and my shots usually penetrated both walls of the can, being stopped only by the paper cone being dragged into the entrance wound.

Feel free to edit this and stick it on a webpage.

I've had some experience with this. A properly made wooden dart is just as effective as any other projectile for hunting small game and some medium game, such as opossum, racoon, fox, (though I would probably only go after medium game under true survival conditions) A wooden dart made like the Southeast Indians did is what I'm talking about with the darts about 1 foot to 21 inches long and about 1/8 up to 3/16 inch in diameter. A complete description can be found in AMERICAN INDIAN ARCHERY by Reginald and Gladys Laubin. I believe that Benjamin Pressley also has some material on these sort of darts. The steel wire darts are great for practice, and familiarization and will also kill game, but they make a narrow wound channel and sure take their time killing. One guy I read about got around this by making his steel darts about 10 inches long and would pin his game to the trunk of a tree. The ball stopper kept the game from getting away until he could get in close to finish it off. I'm a bit more squemish than that and prefer wooden darts for a quicker finish. Poison is another avenue, but really not necessary for small game use. Read also A SPORTING CHANCE by Mannix. He took a ground hog with one Cherokee blowgun and wooden darts, and a bobcat with a Dayak blowgun with unpoisoned darts.

Welp, the Latin American natives use curare (sp?) as a poison on their darts.

And there was a tale going on during Viet Nam about some of the folks in the area tying a piece of yarn to their darts. It seems that they were bagging monkeys with a poison that wasn't quite instant acting. They needed to slow the monkey down or it would run off into the brush. The dart would be shot at the monkey's abdomen and at the pain the monkey would look down, see something poking out of its tummy and try to poke it back in. Seemed to occupy the monkey while the poison did it's job.

I'm not at all sure of how true the story is, but it was kinda fun.

pokin in my yarn

Merv

The blowgun, at least the primitive one I have made and used from cane like the Cherokee used, is used mainly for hunting small game. I have hunted squirrels and birds mainly. Darts 6 inches long fletched with thistle down or feathers are more than adequate for going through a small animal's body. There are accounts of the Cherokee hunting deer, though by going for the deer's eyes, blinding him, chasing him down and finishing him off. North American primitive peoples have used blowguns for thousands of years for hunting small game successfully without poison tips. Now, in South America they use poison tips for hunting monkeys, but that is because the monkey has a more complex nervous system and requires the addition of poison to the tip.

I can send you some info on making and using blowguns, if you like, just let me know your snail mail address and help me out with whatever copy and mailing costs I have. I also will be teaching a class on making

them next year in the Charlotte, NC area, if you're interested. Get on our mailing list to keep posted of when our classes are, if you like. For more info check out our homepage at TRIBE <http://users.aol.com/tbprim1/Tribe.html>

If you have evidence of North American peoples using poison on their  
blowgun darts I would like to have it for it has been my persuasion from  
my research that poison was not used on this continent. I myself have  
hunted successfully without poison tips, small game that is. I used a  
blowgun I made from Rivercane and thistledown fletched darts.

I bought what I thought was an old South American blowgun two years ago.

The blowgun was only 5 foot long and the central hole was quite large  
compared to other blowguns in my collection. It came with a beautiful

primitive woven bag that was full of clay pellets about the size of a large pea. I guess the South American Indians must have shot and stunned small birds with the clay pellets to obtain feathers for their arrows, headress, etc.

I've no experience with that kind of blowgun, and no natural cane that lives in my area(Las Vegas high desert). Yet I've used several diferent types of blowguns, the smallest was .38 inches in inner diameter. The modern commercial blowguns run in two main i.d. .40 and .625. For hunting if I were to do so, I would use the .625 and Cherokee style wood splint darts for small game up to the size of woodchuck. Mainly I build these similar to the description in Laubin's book on Native american archery. You can do the same thing with the .40, but there seems to be more air resistance. The main advantage to the .40 is that common push pins can be used for indoor practice with a dart board. I've used white man's cane(hard copper or conduit piping) to build from scratch blowguns of roughly .50 and find them to work rather well. I imagine it could also be done with a straight sappling of about 1 1/2 to 2 inches in diameter carefully split in half lenthwise with bone wedges and with a stone or bone scraper a groove could be made to each half, then both halves glued with pine pitch and lashed with bark strips and cord. Of course a source of bamboo or southeast river cane such as Benjamin has access to will make the whole process easier and much less laborious. I've never purpously gone after live game with the intent of killing with sharp darts, but I do find the stun darts in .625 to be very accurate for chasing cats in heat from under my window, and once hit and stunned a bird with one of these darts from 25 - 30 yards away after foolishly accepting a dare from my younger son. With a quiver of appropriate darts I would not hesitate to hunt for small game.The darts that come with modern blowguns will kill small game but are thin in

diameter, and are fairly short. They also have the nasty tendency to stick in wood so hard that only pliers can pull them out. A longer, slightly thicker wooden dart will hit with more shock, and with their longer length will keep game from returning to their burrows, and will not stick in trees to the same point that wire or nail darts will. Well, I could write more but I am probably telling you stuff that you already know, just just relating my own experiences with blowguns.

> crazy when it comes to survival techniques...

Hmmmmmm. Interesting idea, that. Not at all what I was thinking of. Rather my method is a little bit more...cleaner. ;-) I've been to the old building where we used to shoot the darts with this type of blowgun, and the darts are still in the ceiling! That was some 20 years ago! Man, they don't clean ceilings, do they????

And yeah, I was thinking about your situation when I suggested it. Just don't shoot the nurses or they'll sic the old battle-axes on you instead of the cute young ones. :-)

Anyway, what I was thinking of was more along the lines of: cut a triangle of paper, roll that around and tape it with a thin piece of tape, just enough to hold it. From the open base of the cone thus created, insert a pin into the cone's apex and on out. The head of the pin will keep it from going all

the way through. Oh, and obviously, you have to be sure you make the cone just a very, very little bigger than the straw inside diameter. Thus:

Of course, the cone is more shallow than that, but you get the idea. The cone will actually have sides at a 45 degree angle or so. We've also made the cones out of tape rather than paper with just as good effects. Your idea of the spitball and sticking the pin thru it would be easier, but might be a bit more messy. You'd have to make like a horn player after a bit and drain the straw. ;-)

You can make a blowgun the same way, using bamboo skewers or slivers of wood and feathers or paper or whatever.

No, left and right they are the same length, but the cord connecting Y at the midpoint of the X-X cord is SHORT, perhaps 1/4 the X-X length. It is also a smaller stone!

This is not gospel. Many variations might be perfectly legitimate. I don't remember where I got my specification, an encyclopedia perhaps.

Congratulations on the new mailing list. I look forward to its topics.

The insect-as-food question is of interest to me as well...

BLOWGUNS! We reviewed them 6 weeks or so back. They are NOT throwing weapons, so I ask that we not spend too much time on them. They are fun though. Another fletching suggested back then was to glue a small ball of cotton to the dart, and then wrap the cotton (squeezing it to the right dimension for the pipe) with thread.

> For thrower, send a HELP command to:  
I have been taught by Steve Watts (Aboriginal Studies at Schiele Museum, Gastonia, NC) that the way to throw a bola with three weights is to place your index and middle finger respectively one each between each string as it hangs down. Keep it from tangling and launch from the hip with an overhand throw. You will know it is thrown properly when all 3 weights spread out in flight, rather like a hand flying and reaching out as it flies toward its target. Anything it hits it will wrap around and bring down. These were thrown into a flock of ducks by Native Americans, and probably other primitive people, when a duck fell to the ground it was then clubbed to death.

The length seems to be important from my experience throwing them. I find that 4 inches or so past your elbow, measure from the end of your arm upward, works pretty well. The cowboys of South America (gauchos) use a 2 weighted bola that is about as long from end to end as they are tall to throw at the legs of runaway cattle, but they are throwing it from horseback.

I can snag a stationery target pretty well and someone's legs, running, but I definitely have got to get out and take game with one yet. I sold one I made to a guy in the San Fernando Valley in California and he snagged a jack rabbit on his first hunting trip! The same guy also hit a rat walking on a wire across a neighbor's pool with one of my slings!---Benjamin (benjamin@perigee.net)

Yes, I throw it from the center. I have better success with this method. I have even make a hadle to grasp in the center sometimes from braided leather. that works well, too. As far as the gaucho's, yes I have seen their method of throwing. The first time I saw it was at a display at the Smithsonian Institution. That display depicted a 2 weighted bola and the thrower was grasping one of the weights to throw it. Now, I have had luck throwing a 2 weight bola in this manner, but not a 3 weight bola. I don't dare say, it can't be done. I just haven't had succes throwing a 3 weight bola in this manner. They also throw a very long bola, from what I've observed. I assume they are able to do this because they are throwing from horseback. All I can say is give it a shot. If you'd like to try out one of my 3 weighted bolas maybe we can trade out something.

I've lost the original posting, but someone mentioned a short two foot bow. If backed with sinew, hickory, or rawhide this bow should be able to shoot a 12 inch arrow( or at least allow a 12 in. draw,) but might be even better as a survival tool than a slingshot for taking small to medium game. Any thoughts on this out there. I think that I would prefer a 3 to 4 foot bow myself and at least a 20 to 24 inch draw.

I made this bow out of cedar and its draw was about 11 inches. This morning, however, I awoke to a cold blistery morning and I found that as air temperature decreases, so too does the draw on a bow. --sulk -- Might start a larger one tomorrow though.

Jeff

>>Jeff, although I never saw the original posting to which you are referring, I can take a few guesses at the benefits of a short two foot bow. It seems to me that the shorter bow would be easier to manipulate (i.e. carry, conceal, etc...) in a stalking/hunting situation. The bow and the arrows are held easily against the body allowing for unrestricted movement through and around obstacles. It also seems that a 12" arrow is much easier to make and eventually replace in a survival situation. My experience is limited to the longer bows but this now has my interest. I suppose, for the true 'off-trail' hunter, a 12" draw is all you would need!<<

I am sure there are many more experienced archers out there with more information on short bow applications, but here is my experience. I made a 24" bow of fire-hardened oak. The main advantage of such a bow is that it can be made in an area with not a lot of straight wood of the

right length. You can almost always find two feet of straight wood. The main use for this type of bow is in set hunting. Set hunting is hunting from a camouflaged position along the side of a trail or run. Because of its size, the snap bow is not incredibly accurate. Set hunting fortunately is typically very close range and requires a hard fast shot. My oak bow draws about 35 lbs, draws about 14", and has a problem hitting much beyond 10 feet. I can hit a milk carton pretty regularly at 8', nbut forget 15'. It is a limited application bow, but a nice one to have in your repositoire. By the way, set hunting of this nature is an art form that requires enourmous skill and patience. You must de-scent, stalk into an area, camo yourself without disturbing the landscape, and then sit motionless for hours. When a deer finally ables by, you have to very slowly move into firing position. Have I done it? Only in my dreams. Deer are very wary. It is a tough way to hunt. I believe it would be possible to use it for stalk hunting, but you would have to be very good to get within 10' to where you could actually hit anything. It does not get hung up in the brush however. They are fun to make and shoot however.

Kevin Reeve

Just thought I might start some discussion on bows. As a college student I am very excited that it is Christmas break and am spending as much time as I can working on skills. Amongst other things I have been working on bows. Yesterday I made a small eighteen incher that broke while I was tillering. Today I made another eighteen incher that broke while I was shooting my cousin (serves me right). I also made a bow about two feet long. Works real well. I have been shooting pillows with the blunt arrow I made out of a sliver of maple and it is good to about thirty feet.

I was wondering, does anyone have any experience with making a bow from store bought wood? The small bow I was shooting my cousin with was made of a cedar fence post. Seemed to work well. It looked like the outside was all one growth ring but it was hard to tell. Anybody ever just gone to the saw mill and bought a four foot length of cedar to make a bow?

Thank you and I really enjoy this list. Anybody know the request address for the thrower list?

Jeff

It is best to harvest your own bow woods or purchase from a bowyer. I recommend the editor at Primitive Archer and Wilderness Way magazine. He has a bowyer supply business called Bittercreek Bow Works. You can write for his catalog at: Bittercreek Bow Works, P.O. Box 203, Lufkin, TX 75902-0203, Phone: (409) 632-8746. Also here are a few other suppliers: Barnett Crossbows, Barnett International, Inc., P.O. Box 934, Odessa FL 33556, Phone: (813) 920-2241

One of the world's leading crossbow manufacturers. Recurve bows and accessories. Catalog available.

Bear Archery, Inc., 4600 S.W. 41st Blvd., Gainesville, FL 32608-4999

Founded by Fred Bear. Catalog jam packed with archery equipment and information on bow hunting.

Charlie Thornton, 3124 England Dr., Fayetteville, NC 28306, Phone: (910) 425-4652

Bowyer, carver, flintknapper

Cliff Rhodes, 7514 Kisco Dr., Fayetteville, NC 28303

Unfinished bow staves, Hickory \$59.00. For more information on various staves, etc. available send business sized SASE.

Little River Stickbows, Rt. 2, Box 276-B, Hwy. 87N, Spring Lake, NC  
28390, Phone: (919) 893-9852 or 497-6424

Various primitive and wooden bow supplies for the bowyer and archer.  
Steve Chattin, Rt. 2, Box 186, Goodview, VA 24095

Primitive wooden bows, staves and arrows.

Hi Jeff,

Thanks for starting a discussion on bows. Again, I would suggest that  
you break down this immense topic into several smaller, more specific  
parts, such as wood choice, tillering, etc.

As far as your lumber question is concerned, I think you would have poor

luck because you want to make a bow with the part of the wood next to the bark. This part is always removed to square off the wood before sawing and going to the lumberyard.

A small sawmill, however, might be able to cut you some wood including the outer part.

To join the thrower list (I love this list too), look here:

<http://ic.net/~tbailey/Primitive.html>

This is Ted Bailey's primitive technology page which includes how to join the thrower group (and has other great links and other lists too).

Have a nice day.

It has been 5+ years since I have made contact with Old Master Crafters.  
They supply all kinds of hardwood strips for laminating bows. I used to  
buy the wood to make boomerangs. I don't know if the address is still any  
good, but you can try:

The Old Master Crafters, Inc.  
130 Le Baron St  
Waukegan, IL 60085

I like Three River Archery supply ("World's largest  
Primitive/Traditional Archery Supply"):

<http://www.3riversarchery.com/index.htm>

They have all kinds of bowmaking materials and tools - also assorted  
goodies like sinew, flintnapping supplies...2,500 items.

Folks might also try Native Way. Sorry I do not have the web address right now, but you can get it by e-mailing at [nativeway@bkbank.com](mailto:nativeway@bkbank.com). These guys have a good supply of primitive bow and arrow making and flintknapping supplies, as well as finished products.

Hi All!

I just ran across the Three Rivers Archery web page at:

<http://www.3riversarchery.com/index.htm>

Its a pretty cool page and they have some really neat knapping stuff. I'm getting a few friends to go in on a big order and was just wondering if anybody on the list had done business with them. Also, does anyone happen to know about laws about importing animal parts (antler & sinew). I'm in Canada, eh?

Tim

Subject: Arrow Cane

Content-Transfer-Encoding: 7bit

Content-Type: text/plain; charset=us-ascii

Status: U

X-Mozilla-Status: 0001

There are 2 types of bamboo or cane native to North America  
(right?), *Arundinaria gigantea* (Giant Cane) and a smaller one the name  
for which escapes me. The ethnobotany search showed giant cane as the  
cane used for arrows but I have been told by at least 2 sources that it  
is the other. I am having trouble locating the correct name in my notes  
and wonder if anyone could help me out.

My intent is to cultivate/propagate both for use in various projects.  
Since both are native to the area I would not be risking environmental  
collapse, however, no one knows where any is growing. It seems that in  
the rush to develop farmland and all that has come since, the canebrakes  
have disappeared. Can anyone help me with a source for propagation?

Many thanks in advance.

--

Sincerely,  
Barent

My "Last Whole Earth Catalog" - circa 1970 - says the last word on bamboo is called (oddly):

Bamboo  
Robert Austin, Dana Levy and Koichiro Ueda  
John Weatherill Inc.  
1970, 215 pgs.

Maybe ask an internet booksearcher if it's out of print. I generally ask Lawrence Peryer at TheSpaceBetween . There are others (Amazon maybe). Happy hunting.

Chris

Here is a copy of an article that appeared in one of our former TRIBE newsletters (TRIBE NO. 17, Mar.-Jun. 1995) that I think will answer your question as well as some additional info on the uses of cane:

Sam Lawson (TACACHALE Programs, Ranger, GA) sent this very informative article to us. It is on the many uses of River Cane. It is written by Dr. Hampton Rowland a native Georgian who retired from several years of teaching in the Anthropology department at Florida State University in Tallahassee, Florida. He held a M.S. degree from that university with a specialization in primitive technology. Sam also informs us that: "The courses he taught there on this vital subject were among the best of this rare academic course taught anywhere in America. He combined the knowledge and skill of a lifetime in his spirited and fascinating lectures on the subject. Dr. Rowland spent his last years in Athens, Georgia and inspired many of us now in the field of primitive skills."

Cane Talk

By Dr. Hampton Rowland Jr.

--1989--

Whenever I talk about Southeastern Indians I try to get people to think about other material than just stone tools and pottery. These materials certainly make up the major portion of what we recover archaeologically, but form only a small part of the items used by Southeastern Indians. This is one reason I have spent much time studying the use of cane in the Southeast and will try pass on some of this information.

The first thing to understand about cane in the Southeast was its

abundance. Almost every early traveler had some remark about cane. Benjamin Hawkins made a survey of most of the Indian villages in Georgia and west Alabama in 1799 and he remarked on cane being readily available in over half of the locations he described. Most of the living sites were all along streams or rivers where cane grows abundantly. Perhaps you may wonder why we no longer see the huge canebreaks that we described by the early writers. The tender shoots of new cane have been described as excellent cattle fodder and the cane can be destroyed by over grazing and by hogs rooting-out the roots. Cattle and hogs came in with the Europeans and were not native to the Southeast. D'Iberville and others state that the cane breaks could be easily cleared and provided rich and, even when green, can be cleared far easier than a stand of timber. Thus most large cane breaks disappeared due to animals eating it and to an increased need of rich agricultural land.

We need to consider some of the characteristics of cane to understand why John Swanton considered it one of the most important of all raw materials used by the Southeastern Indians. There were two native canes. The largest is *Arundinaria gigantea* - giant cane- which can grow to over 25 feet tall and with a common diameter of up to two inches, although D'Iberville describes some cane along the Mississippi River as large as six inches in diameter. The other native cane species, *Arundinaria tecta*- switch cane or river cane- grows only up to 10 feet high and no larger than 3/4 of an inch in diameter. In a given grow of either, there will be tremendous size variation depending on spacing, available light, and soil fertility.

On the scale of individual pieces, the differences in cane include variations in diameter, distance between the joints, straightness, and the degree of taper. In addition, the internal structure of cane provides opportunities for variation in usage. It is these that permitted cane to be used in so many different ways by the Southeastern Indians. The larger sections can be very stiff and strong. Cane has flexibility with this strength, even to the extreme tip of a fish pole, for example. Individual joints of cane provide various size containers or, with the joints removed, tubing in various lengths and diameters.

One characteristic of cane that is often unrecognized is the availability of uniform or nearly identical pieces. We are used to having uniform manufactured materials, such as two by four inch lumber, for construction purposes. Finding trees of consistently the same size was a problem for the Indians. But in a cane patch, with a little selection, they could find two, a dozen, or perhaps fifty almost identical pieces.

A final characteristic of cane is the ease and accuracy with which it can be shaped with stone tools. For example, cane can be split readily into strips of various widths to prepare materials for baskets or mats. Another common basket material, white oak, requires cutting trees into logs and then splitting the logs into strips-a very difficult process using only stone tools.

A final characteristic is the effect heat and dryness on cane. Green cane can be straighten or bent by applying heat and bending pressure. It will retain the new shape, straight or bent as desired, when cooled. Strips can be soaked for flexibility during weaving and then will become rigid again when dry. Green cane does not readily burn and can be used to make a grill over a fire for smoking of meat. Although not yet documented historically for the Southeastern Indians, the cooking of food by stuffing it into sections of green cane and placing the sections

over a fire is common practice with in the Far East and may have been practiced here. Finally, dry cane burns well as a fuel and gives off good light.

Some important specific uses of cane in the Southeast include:

**Weapons:** Cane was probably the most common material for arrows in the areas where it was available. Garcilaso de la Vega gives some dramatic examples of penetration and wounds from cane arrows. Cane was also used for spear shafts.

**Food Collecting:** Cane was used for fishing poles, of course, but was also used as set-poles where the fish would struggle against the spring of the pole. Cane was used for spring style snares and traps of all descriptions, using the ability to split-out the cane for funnel-shaped entrances. While not described in detail in historic documents, it would have been the best available material for fish weirs and other fish traps. There is an interesting historical reference to using circles of cane around rawhide to prevent animals from gnawing through snares.

**Baskets:** Baskets were a very important use for cane. They play a major role in food collecting and storage. The construction of mounds required the use of baskets and it is quite likely that these were made of cane. The Southeast Indians excelled in basket making during the historic period and their crafts are still collected today. Early Virginia settlers refer to households needing sets of Indian baskets so tightly woven they could hold water. I know of no references to cooking in baskets with hot rocks among Southeast Indians, although this practice was used by California Indians. We might assume, however, that baskets were used long before pottery was invented and were used for cooking.

**Construction:** Palisades of cane were constructed in Mississippi around villages for protection. Fences were also constructed of cane during the historic period to confine. Cane was woven horizontally between vertical supports for wattle and daub house construction. There are also references to cane mats for the support of the clay on the walls of houses. The De Soto accounts of 1539-1542 refer to houses and temples covered with cane mats. A very interesting description of cane used for roofing in the same fashion as ceramic tile is recorded by D'Iberville in the early 1700s.

**Household:** Cane mats were used in many different ways by Southeast Indians. Several early authors refer to the placing of mats on the ground for covering the floors of some houses. Beds were constructed of parallel canes tied together placed on supports and covered with cane mats. Cane mats were used to wrap the dead and one reference mentioned a cane tent or roof placed over the body. Cane was used in cooking for stirring, cutting, and dipping. Ritual drinks were blown into using cane. I have observed the Black Drink being prepared by a medicine man blowing into the drink which caused it to froth up before serving. A hollow length of cane would be especially valuable with an open fire. It would be used to blow upon the embers to get the fire started up and create a hot fire for cooking. In Asia, a blow pipe was an essential tool of the country women cooking over charcoal fires. Joints of cane provide some of the best small containers for spices. In many areas of the world

bamboo is the principle container for carrying water.

Fire: Cane has been used as torches since prehistoric times. In the Salt River Cave of Kentucky the remains of cane torches were found that were carbon dated 2000 - + B.P. One of my students conducted an experiment and found that he could make cane torches that would last for at least 45 minutes and provide light that he could read a newspaper at 10 feet. D'Iberville describes a torch made of a bundle of cane 15 feet tall with a diameter of two feet which provided light for festivity. The Creeks commonly used a star of logs but for certain ceremonies would construct a spiral of cane that would burn for some time and place a time limit on the conference.

Miscellaneous: Cane was used in many other ways by Southeast Indians. Blow guns were made of cane in historic times, but may be of African or South American origin. Canes were used as shuttles for net making and for loom weaving, which also may be a post-contact use. Stems for clay pipes were mentioned as the first references to the use of tobacco. Punctuation on pottery by cane is a common design element. Cane was used to bore holes for stone pipes with water and sand. Cane was, and is, used for making musical instruments.

Jeff Gottlieb (Massapequa, NY) also sent us some interesting information on Rivercane and its Asian cousin Bamboo. This information is derived from Smithsonian magazine, October, 1994.:

Before European colonists arrived in North America, *Arundinaria* grew in vast canebrakes. Early American botanist William Bartram described the thickets as appearing to have "no bounds but the skies." Indeed, they stretched over what are now 19 states in the South, Midwest and East, and as far north as Ohio.

Explorers on horseback or on foot cursed the stuff, which they found nearly impossible to get through. Pioneers, however, taking note of the luxuriant growth, reasoned that a good stand of cane meant good soil for crops. They cleared the land for plantations and homesteads by cutting and burning it. When they were through, the big cane was nearly gone for good.

As far as is known, *Arundinaria* supports no interior ecosystem like *Guadua*, but before their razing, the "brakes" provided cover and sustenance for bear, deer, turkeys, small game, perhaps even bison. Bamboo seed, with a nutrient quality exceeding that of both rice and wheat, was a food much sought after by man and beast alike. In 1850 a diarist wrote of bamboo and animals near New Harmony, Indiana: "Fox Island was full of game from my earliest recollections up to the year 1850 when the cane ... went to seed and then all died. The seed grew in clusters and resembled oats, and all the animals and fowls got rolling fat from eating this seed."

The extirpation of North America canebrakes- and the seed and the shelter they provided- may have hastened the extinction of at least two North American bird species: the Carolina parakeet and the passenger pigeon. The pigeon relied heavily on the brakes for food and shelter. In 1813 painter John James Audubon witnessed a flight of pigeons that numbered more than one billion, so many that the sun " was obscured as by an eclipse." The passenger pigeon became extinct in 1914, the Carolina parakeet, followed four years later. Ornithologist Daniel McKinley, considered the leading expert on the parakeet, says the

beautiful bird's erratic range (Florida to New York, and west to Colorado) was linked to Arundinaria. "Like all parrots they lived a long time [20years] and probably didn't breed every year. In nomadic fashion they may have followed the bamboo for a place to raise a family."

A third bird that depended on the big cane for nesting is Bachman's warbler, hovering so close to the edge of extinction that the last undisputed sighting of it was in Virginia in the 1960s. Louisiana State University ornithologist James Van Remsen, Jr. theorizes that the bird's recurved bill may have become specialized for gleaning bamboo. At any rate, the warbler lived in close association with North American Arundinaria.

Subject: Sinew processing and bow string

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

Just a question.....

I've made a few long bows over the years and I've always tried to use sinew strings on them. The strings work for a few months and then blow. I was wondering if anyone had any suggestions on the preparation of the sinew that might enhance it's longevity.

Of the techniques I've tried, this is what has been working best for me:

Use a tendon from a cow's neck or rear leg.  
Scrape to clean it of loose material.  
Urine soak for 24-48 hours.  
Wash thouroughly with clear water, dry.  
Set aside for months in a clean,dry dark place.

After the tendon looks translucent, I break it down to the fibers by  
pounding and/or stripping.

I double twist the fibers to make the string. Once the string is set, I soak  
it in my mouth for an hour or two. The saliva seems to bind the string.

I make the end loops for the bow limbs and serve these with more tendon.  
Thats it.

Any suggestions?

By the way guys, woodchuck raw hide is also supposed to make good bow strings. Just cut in a spiral fashion to make a thin thong braid together into the desired length. How many single thongs do you need to braid together to make a bowstring of a particular strength?

Oregon bows, especially along the west coast, were usually made of yew, although Juniper, Ash, Chokecherry and Mountain Mahogany were also used. Most Oregon bows were backed with sinew for added strength. These bows generally had a wide, thin elliptical profile with a narrowed handle. The bow length ranged from 36 inches to 56 inches.

Western Indian boyers usually produced excellent equipment prior to the introduction of the horse. Indians who hunted on foot usually got just one shot, so they had to ensure ideal performance with a well balanced bow and straight arrows.

if you want it to be functional make it 56 inches or longer. 36 is too short

A staff sling is not quite like a lacrosse stick. On a lacrosse stick, the pouch on the end is fixed in place. On a staff sling, the pouch is only attached on one end, and it hangs below the stick when held horizontally. The other end is just hooked over the end of the stick, and it comes off when

thrown.

Perhaps this simple diagram will help. The end of the pouch that is closest to the handle end of the stick is attached. The other end has a loop or some means of hooking it loosely on the end of the stick so that it can release the projectile.

I'll send you a file,(may have already done so) on the fustabal, I'm  
familiar with Lacrosse sticks though I've never played myself. What pray  
tell is a hoopak? I found this sight on a SCA site.

# The Staff Sling: Guidelines for Construction and Use

**This article is intended as an introduction to a missile weapon which was extensively used from antiquity until the high middle ages, notably by the Carthaginian, Vandal, Roman, Byzantine and other armies of the continent. This weapon was called the fustibalus (in Latin). To the right may be seen an illustration from a manuscript in the Bodleian Library in Britain, which shows maritime combat with the fustibalus. It is also mentioned in the Codex Antlanticus of Leonardo da Vinci, who experimented with various forms of it as an exercise in martial engineering.**

**The Fustibalus was about one meter in length, and boasted a range of some 550 feet! Accuracy with this weapon comes only with practice, and its use among the romans was restricted to auxiliary troops for this reason. The trebuchet, a siege weapon much beloved by medieval engineers, was nothing more than an enormous staff sling that employed a counterweight**

for achieving torque instead of arm and shoulder. The missiles launched were, in antiquity, referred to as glans. These were clay and/or lead pellets, oval in shape and generally flattened. They often had the names of enemies, pictures of scorpions and other martial graffiti inscribed or molded on them. Those samples remaining today are about 1 1/2 to 2 1/2 inches in length and 1/2 to 1 1/2 inches in width. These glans weigh around two ounces, though examples exist weighing up to five.

So how do I make one? Take a rattan stick about 30-40

inches long and make

a leather 'pocket' as shown in the diagram. By securing one end some 6-8 inches from the tip (with the thonging), you'll set the range of your particular sling. Remember, you're going to lay a slightly flattened, never round, missile in this pocket and swing the staff 180 degrees. The point of release, and thus the range, will depend on the length of the thonging holding the pocket. Only trial and error will help you set your range. The other end

**of the pocket MUST slip off the tip of the rattan smoothly - it may be nessecary to smooth the place where it clears the end with some sandpaper. Always use tennis balls for SCA combat which have been slit on four of their sides. You could even attach red/yellow streamers to represent the clay incendiary grenades the Carthaginians threw from theirs. Of course, you'll need to duct tape before slitting. Hope to see you at the Siege!!!**

My conclusions thus > far: > > 1- Like Jim Merlini, I too have preferred the single vertical turn and > immediate release. My thinking is that no animal that I know of will > stand around while some primitive human being is busy spinning a stone > for several seconds over his/her head. Even a single vertical move is quite noticeable to some animal you are hunting. I think the sling is more practical as a weapon of defense against animal aggressors, rather than for food acquisition. For example, chasing wolves away from sheep, or foxes from chickens. As for accuracy, talent is as much a factor as skill I'm sure. I seem to be able to achieve relatively good horizontal or vertical accuracy, but not both at the same time :-). Yet I'm told there are people who can repeatedly hit a target the size of a small melon at 60 yards. > b) When realistic food gathering is the only concern, what are your > preferences? As you said... First for very small game at relatively close ranges (20 meters or less, squirrel, rabbit, etc.) I would say the slingshot (a good one), or a light crossbow with small game points. For somewhat larger game, the crossbow or longbow if ranges can be kept under about 50 meters, a rifle otherwise. Remember where food gathering is the aim, there is also trapping to be considered... > c) Any literature you know of which addresses these concerns? There are a few magazines, and some web pointers. Look at Wilderness Way at <http://www.pioneerpc.com/wildernessway/core.html> and also <http://home.earthlink.net/~nyerges/> > b) What's the current thinking on the various throwing weapon It is pure sport for me. charset=US-ASCII Status: U X-Mozilla-Status: 0001 Oops! I've been meaning to comment on a post of a week or so ago regarding projectile weights. Someone had  
spoken of ammunition in the 30 gram range, that's a little over 1 ounce. Personally I do not throw ammunition so lite. I like something minimally about twice that,  
and my preferred weight is anywhere from 4 to 6 ounces. As for throwing styles, I have experimented with underhand, which tends to lob the projectile. I had read  
that this throw was primarily for heavy weights meant to be dropped into a crowd (ancient advancing troops for example). I can also throw with a single over-hand  
motion, sort of like throwing a grenade (stiff arm), and this works very well, but my favorite is still the helicopter whirl where the sling spins overhead in a  
horizontal plane and in the last 1/2 turn the arm extends to provide kinesthetic sense of where to release, but still in a horizontal plane above the head. Like knife  
throwing or anything else, accuracy is as much a matter of innate talent as practiced skill. I know there are people who can hit an 8 inch target consistently at 60  
yards! matthew rapaport Philosopher/Programmer at large KD6KVH mjr@crl.com In God we trust. All others we monitor! quine@dfw.net

>Steven Krom >>----->For thrower, send a HELP command to: Steven, Yes, I  
started with the underhand throw. The main problem I find with it is that I tend to side arm it a bit and my throw will go off to one side of the target. I really think it  
is the throw of choice for long distance slinging, but it has a high looping trajectory. I've read that it was the throw of choice for teaching Roman troops to sling with

only one movement and no wind up swings. I am working on the pocket section of my fiber sling, Instead of wool yarns I used #18 nylon sein cord in yellow and white. I'm afraid that it's much too slick to use the 16 strand braid worked up as mentioned in the book on sling braiding. So, after making the finger loop, I separated my strands into 4 bundles of four strands each and did a 4 strand braid worked down until I had a length long enough for the retention cord. For making the pocket I'm using a separate length of yellow sein twine and the finger weaving pattern copied from the article on a sling pocket of the paleo indians found in Lovelock cave here in Nevada. I'll let you know when I'm done. Touch of the Bear JB

> For thrower, send a HELP command to: I use a different method of throwing a sling, at least I haven't yet heard of anyone throwing this way, unless they were one of mine or Robert Likas' students. I swing the sling in a circle around my head, line up with my target as it passes in front of my eyes. I then turn the circular path into a quick whip and overhand throw at the target. This is more natural, if you think about it, you are usually used to throwing overhand without a sling, so the sling becomes an extension of your arm. ---Benjamin (benjamin@perigee.net)

the list;; How did you determine > the length of your sling cords? By expediency. I'm an overhead slinger, i.e. I swing the sling horizontally overhead when I shoot. However, my prep is to put the stone in the pouch, let it hang loose, then bring it up to firing/moving mode by swinging it back once and on the forward return up and around. Thus, my maximum sling cord must allow me to clear the ground when my hand is at about waist level. Bill B.

What=20 > are your thoughts (or anyone else) on the ease with which a beginner can=20 > become accurate as compared to a bow, for instance? Well, this depends, as on all other feats of accuracy, on what the beginner 1) has a "talent" for and 2) has a desire to apply himself/herself to. That said, I use both bow and sling, so think I can compare the two somewhat. I think that a raw beginner, with no knowledge other than that from watching movies, and with a serious interest in mastering both would find both to be of the same difficulty. The reason I say this is that the arrow is a little more stable, and the bow is quite easily applicable to repetition. That is, I can pick up the bow, put my feet just so, hold the bow just so, draw to an anchor point just so, align the target against the bow just so, and shoot. BUT...I can only shoot so many times before I get tired, and the minute I get tired, my aim and form will suffer. Now with the sling, it is NOT an easily repeated situation BUT the ammo is more plentiful and the areas where you can shoot are far more plentiful AND you can carry the sling with you all the time and so shoot whenever you have a moment free and a good site. With the bow is the ease of repetition, with the sling is the abundance of practice. If one had to learn alone, just pick up the equipment and try to work it out, then I'd say the beginner would have better luck with the bow, at least at first, simply because of the ease of repetition. The difficulty of the sling lies primarily with not being able to recall as accurately as with the bow exactly where your hand was, what angle your wrist was at, how fast you were slinging, where was your arm, etc., etc., when you release the stone. This is without anyone to provide comments, assistance, or instruction, as if you were out in the middle of the plains all by yourself, the nearest town 100 miles away and there on the ground lie a bow, arrows, and a sling. With assistance and instruction, I'll stand by my second paragraph, that they are equally easy to become accurate with, for someone who really wants to learn. Bill B. Transfer-Encoding: 7bit Mime-Version: 1.0 Reply-To: thrower@dfw.net Content-Type: text/plain; charset=US-ASCII Status: U X-Mozilla-Status: 0011 When we  
kids made slingshot pouches out of leather (invariably castoff shoe leather and hence a bit stiff) we cut two slits in them, about one-half of the distance between the  
center of the pouch and the attachment points for the rubbers. This made the pouch fit more closely around the rocks or marbles we used for ammunition.  
Sometimes we connected the two slits with a third slit, creating an H-shaped slit in the middle of the pouch, to allow a rock, especially an irregular pebble, to settle  
even deeper into the pouch. The split pouches on traditional slings undoubtedly are meant to do the same thing: contain a missile snugly and securely until the  
instant of release. (I can imagine an ancient hunter being seriously irritated when dinner got away because the stone fell out of his sling.) You could even gauge the  
size of missile the slingmaker customarily used by measuring the gap in the pouch.

Folks are talking about staff slings and how they might be made. A Trebuchet is, well, kind of a staff sling. Well, maybe a pivoted staff sling on a support of some kind weighted at the end away from the sling... Herre's some pages that show Trebuchets. <http://www.cybernautica.com/hurling.html> One under construction <http://www.eclipse.net/~dimona/libtreb.html> Interesting pseudo code describing a trebuchet. <http://www.wnmu.edu/trebuche.htm> Three beautiful pictures of the launch sequence of a trebuchet. Note that this siege engine is really just a sling. <http://www.iinet.net.au/~rmine/gctrebs.html> Don't miss their "Cheesechucker" Good info on staff slings and the traction trebuchet also. <http://www.df.lth.se/~jesper/funnys/archive/trebuchet.html> Good text work. <http://asylum.apocalypse.org/pub/u/zonker/fpp/html/trebuchet.html> Article about Hew Kennedy's Trebuchet. " The heart of the siege engine is a three-ton, 60-foot tapered beam made from laminated wood. It's pivoted near the heavy end, to which is attached a weight box filled with 5= tons of steel bar. Two huge A-frames made from lashed-together tree trunks support a steel axle, around which the beam pivots. When the machine is at rest, the beam is vertical, slender end at the top and weight box just clearing the ground. " From the above url. There's more on the 'net. This was a quick scan of an Alta Vista search. Enjoy! Be careful!!!! Burdine) Reply-To: primitive-skills-group@uqac.quebec.ca, jburdine@PIPELINE.COM Subject: grenade slinging Content-Type: text/plain; charset="us-ascii" Status: U X-Mozilla-Status: 0001 I guess a blackpowder grenade would be a primitive type weapon, but I suspect that it would be best used to drive another creature or group of creatures toward another area. In that case the best way to use a grenade is to unscrew the fuse assembly from the body, remove the striker and replace with a simple strike a light fuse and cap assembly. Remember friendly fire isn't..... and the only thing more accurate than enemy fire is friendly fire. Actually having used both the modern baseball type and the older pineapple grenades, I'll leave using grenades as sling projectiles for the braver guys out there, and "never get into a foxhole with anyone braver than you are". Personally the whole thing gives me the shivers. :-0 ;-) Jim Burdine LV, Nv jburdine@pipeline.com X-Mozilla-Status: 0011 From - Mon Jan 13 21:07:33 1997 Received: from poste.uqac.quebec.ca (poste.uqac.quebec.ca [132.212.11.73]) by chic1.saglac.qc.ca (8.8.2/8.8.2) with ESMTP id WAA25531; Mon, 13 Jan 1997 22:26:32 -0500 (EST) Received: from vaxcha.uqac.quebec.ca (vaxcha.uqac.quebec.ca [132.212.12.12]) by poste.uqac.quebec.ca (8.8.4/8.7.3) with SMTP id WAA02684; Mon, 13 Jan 1997 22:25:07 -0500 (EST) Received: from poste.uqac.quebec.ca by vaxcha.uqac.quebec.ca (MX V4.2 VAX) with SMTP; Mon, 13 Jan 1997 22:23:15 EST Received: from ns2.qnet.com (ns2.qnet.com [207.155.33.10]) by poste.uqac.quebec.ca (8.8.4/8.7.3) with ESMTP id WAA02677 for ; Mon, 13 Jan 1997 22:24:52 -0500 (EST) Received: from Quantum.qnet.com (lanc00-26.ca.qnet.com [207.155.34.56]) by ns2.qnet.com (8.7.6/8.7.3) with SMTP id TAA08283; Mon, 13 Jan 1997 19:29:00 -0800 (PST) X-ListName: PRIMITIVE-SKILLS-GROUP@vaxcha.uqac.quebec.ca Warnings-To: <> Errors-To: owner-primitive-skills-group@uqac.quebec.ca Sender: owner-primitive-skills-group@uqac.quebec.ca Message-ID: <2.2.32.19970114033041.00734c18@pop3.av.qnet.com> X-Sender: diogenes@pop3.av.qnet.com X-Mailer: Windows Eudora Pro Version 2.2 (32) MIME-Version: 1.0 Date: Mon, 13 Jan 1997 19:30:41 -0800 To: primitive-skills-group@uqac.quebec.ca, jburdine@PIPELINE.COM X-UIDL: 853250488.080 From: "diogenes@survival.com" Reply-To: primitive-skills-group@uqac.quebec.ca, diogenes@SURVIVAL.COM Subject: Re: grenade slinging Content-Type:

text/plain; charset="us-ascii" Status: U X-Mozilla-Status: 0011 Personally the whole thing gives me the >shivers. :-0 :-) You bet Jim. The problem was if you can toss a grenade a certain distance, so can they. The stronger arm wins. We tried a number of variations on the grenade sling and finally settled on a three foot para cord tied to the fuse body. We tied a large knot in the middle of the cord and one at the end. Pop the spoon, two rotations and that death grogin was on it's way. No fuss no muss. It had nothing to do with being brave and and everything to do with keeping those buggers out of the firebase. I hate fixed positions. We even made a catapult out of a captured Chinese 82mm mortar. With a number one charge it could toss 30 gallons of jellied gas about 250 yards (fused with an in-air arming contact detonator, natch). Awesome. Sometimes we'd just fire one up to watch the flash. Ancient weapons are sooooo much fun. BTW. the mason jar, grenade delivery is something we adapted from Huey eggs. Ron XX Dr. Ron Hood P.O. By sling, I mean the type David killed Goliath with not the wrist rocket type. Specifically, topics I suggest: What materials do you make your sling from? What length do you prefer (folded)? What technique do you use for throwing a projectile? Have you killed anything with it for food? Is it a weapon, in your opinion , that is hard to master? What are the pros and cons of it as a survival weapon, in your opinion? Here is some of my experience with the sling. It is a weapon that is hard to master. I'm still not consistently accurate with it. It is an extremely powerful weapon, though. Once a friend of mine and myself were throwing spark plugs into the pines for distance (sorry, I know that's not that environmentally conscious. I don't do it as a habit.). I know we were watching them soar 50-75 yards or better. This was on an uncle of mine's property. I was there one day when he was cutting up a pine he had downed with his chainsaw. The chain broke while he was sawing it up. He rolled it over and a spark plug was imbedded up to the glass insulator! I have also plit 1 inch thick pine boards with a stone al little smaller than a golfball from 35 yards. As far as length I like measuring my sling on the average from the heart to the end of my arm held out to my side (folded). I credit my friend, Robert Likas, with this measuring system. He is also who got me started with slings. Historically, for warfare, slingers carried a short sling for close range, a medium

length for medium range and a longer one for distance. For ammo, I choose stones that are roundish, sort of egg-shaped with a flattish side. I lay the stone with the flat side flat in my sling pouch, not on its side as it would seem more natural to do. I have found the projectile to fly more predictably when loaded in this manner. Too flat of a stone will take all manner of unpredictable paths. I have seen flat stones take a 90 degree turn in mid-flight. I have also experimented with sun hardened clay. Robert Likas has experimented with fragmentation projectiles. He has loaded a piece of clay with buckshot and thrown it. When released the force of firing it from the sling it goes to pieces and has the effect of a shotgun blast. ----- Benjamin Pressley

When I was a kid, up until I was about 16 had a car and could go fishing on my own, I did a lot of messing around (a good way to characterize what I was doing) with throwing stuff (sticks, spears, knives, and slings) and made my first slings. I never thought of the heart to hand measuring system but that does come out at about 30-36 inches which is where I ended up. At that time I would buy leather shoelaces for the straps and use soft waste leather from my Dad's leather projects for the pouch. Have used it to harrass a friend in a canoe on a lake so I know that you can heave a good size rock quite a long way. I never got very good for accuracy but I could heave a rock a pretty good distance, 60-70 yards. I used to think it was closer to 200 yards :). I used the thing to scare game towards me by throwing the rock to the other side of brush piles, cedar clumps, etc. We have tried heaving grenades this way but the damn spoon keeps popping off (like it is supposed to) and when you are fumbling around with a sling that isn't a good thing. Yes, yes,... we are experimenting with practice grenades not the real thing. We go that idea from a movie we saw which title I cannot remember for the life of me. I think that you would have to start using one of these at a young age (darn my over protective mother ;) ) to acquire a high level of skill and that at this point in my life I just don't have the time to become proficient. -- Sincerely, Barent Duty, Honor, Country X-Mozilla-Status: 0011 From - Mon Jan

As a result, some of this may well have been covered by others already. However, I can speak from experience on slings, so finally something I feel I can contribute to. Matter of fact, Benjamin, you've probably read most of this over in the Thrower's list anyway. FWIW... Been slinging, on and off, since the age of 7. In general, my slings (after the first one my dad made me) are made out of any material that will work. I like the thongs to be flexible enough to roll up, but have used stiff thongs with success. Folded, I like my slings to be of a length to clear the ground when my elbow is at my side and bent 90 degrees. The reason is that my preferred throwing method is to load, lower the loaded pouch while keeping the thongs reasonably tensioned, then drop it so it swings back and on the forward swing whip it up and around my head. I may use only one swing, I may use several. I can keep it spinning around my head as I move for a better shot or as I wait for the target to get into view. Then I whip it hard around, and when my hand is beside my head, I continue forward to point at the target. The pointing releases the free end of the sling, and the projectile speeds to the target. The other end of the sling has a loop that I wear around my middle finger. The free end is held between my first finger and thumb as I whirl it. My current slings use leather boot thongs and a piece of leather 2" x 3" for the pouch, with the thongs tied snug against the 2" sides. I've used both rectangular and oval pouches without noticing enough difference in performance to worry about it. I'm not sure, as I'm deaf, but I think that the ovaled pouches are quieter. Sometimes the rectangular ones seem to vibrate as I whirl them. I like the leather for durability, mainly. I've hunted small game with it, birds, rabbit and squirrel mostly. I've had limited success, but haven't been using it with the aim of using it to specifically hunt with. If I were to do that, then I imagine I'd be able to bag game OK, up to the level of a fox. Beyond that, I don't know. Of course, this depends on the range as well. However, I have sent a steel ball 1" diameter humming into a tree trunk some 80 yards away and had it hit with a very solid thud, so obviously the size of the ammo affects the range. (Sound effects courtesy of a very impressed group of people I was demonstrating to.) It's not any more difficult to master than a bow, IMHO. I've said elsewhere that both the bow and sling are as easy to master, for one main reason: the bow allows repetition, but you tire after tens of shots while the sling isn't as easy to repeat the exact same motions with but you can practice so many more shots with it, and most anywhere. As a survival weapon...only if you've spent time getting good with it. As with bowhunting, spearing, and other ilk, you need good stalking skills as well. If you work on your accuracy, then birds would be good game for this. However, other methods should be worked on first, as using a sling can expend a lot of energy that you might not be wise to spend yet. One reason I carry three slings with me in my emergency pouch is that they're fun to play with, roll up small, weigh nothing, and have multiple survival and emergency use. For example, I can untie the thongs and use them for snares, lashings, tourniquets, fishing, and so on as well as as a sling. (That's why I like to take more than one in my pouch.) Also good for keeping kids amused. There are several ways to sling the stone, vertically vs horizontally, or a combination. One or more rotations before release. What position is best for your release? There are a few variables, but if you work on one style and get good at it, then add an alternative backup style, using a sling might be a good survival weapon. But it's not one of those weapons that is hard to learn, it just takes a lot of practice, which can be a lot of fun. Plus, it's easily made in the survival situation, usually. As you say, they are immensely powerful. However, I challenge your statement that it's hard to master. I would counter that with the fact that I've taught several people to use a sling with reasonable accuracy (not hunting accuracy, though). Without seeing how you shoot it, I can't offer any tips, but I would suggest that perhaps you're trying too hard to control several variables. Your length seems a little long to me, and if you are slinging vertically, this could well be a part of your problem as you try to keep it from hitting the ground. I'd suggest shortening it to maybe fingertip to armpit and trying that for a while. Then gradually increase it back to the original size if you want to. You're splitting boards with it and all, so you do have some accuracy. Forget the accuracy, just get the movements down smoothly. Keep shooting like that until you can do it without any effort and still pay attention to just the placement of your first finger and thumb, or the angle of

your elbow throughout the whole thing. Once you can do that and still hit within a 15 to 25 degree angle in front of you, then start paying attention to the various variables and work on accuracy. As they say, learn the form first, then apply power. I also found that either horizontal spin or vertical spin have greater accuracy than a spin out of these axis. That is, a spin that goes by the ground beside you to over your opposite shoulder, for example, is going to be less accurate. For height I'll go vertical, for left/right accuracy I'll go horizontal. I've used ammo ranging from spherical to eggish, smooth to rough. I only avoid jagged ends that might cut my pouch from the force. I much, much prefer spherical ammo, I find it's much more accurate. Like you, if there is a flat side, I'll put that flat side against the pouch. But I would much rather shoot spheres and if I have to shoot one with flats, I'll try to find one with as many flats as possible on it. I have two gallon jugs left of my favorite ammo: steel balls, 1" dia., then after that I'll either get more bearings or start making clay balls to sling. But in the field, I'll pass up stones to find those that are as spherical as possible. I also like to put several small stones in the pouch and shoot them all at once for the shotgun effect. This is particularly good with birds and small game, but does need a little larger pouch than my usual one. I've not experienced the erratic flight paths you describe, but this may be due to my avoiding if at all possible ammo with flat sides. The release from the pouch imparts a spin of sorts to the stone, and this may account for your erratic flights. This spin isn't much, but with a flat side that could rotate towards the path of flight, that might make it plane off. Oh, and for size, I like them to be about 1" diameter, but no more than 1 1/2" diameter or less than 1/2" diameter, unless I'm "shotgunning." I think the smallest I've used, even when shotgunning, is 1/8". Probably the most erratic flight I ever had was when I first started. I was shooting stones out into the lake, watching the splashes. I was working on getting the stone way, way up there so I could get a bigger splash. After a couple throws, I did one without any splash. Puzzled, I figured I'd missed seeing it and continued. In a couple minutes, my dad came up to me and told me to move on down the lake or put the sling away. That stone I'd not seen the splash for had gone through one of his friend's windshield, about 80-90 yards...behind me. The funniest flight I ever saw was my brother's first throw. My dad carefully explained to him how to use the sling. He put in a stone, whirled it around his head, and let fly, and hit the piece of wood floating on the lake dead on. Only one problem, he'd misunderstood something and had let go completely so the sling went with that stone. The look on my dad's face was comical. I've also seen people shoot the sling, release it completely, and it gets tangled in a branch, hanging there with the stone still in the pouch! Well, this is probably long enough. I can go into details if there are any other questions, either here on the list or via e-mail. I've made my first fiber sling from yellow and white nylon #18 sein twine(or what we would have called trotline cord in Oklahoma) It turned out very nicely and I'm proud of it. My only problem is that the socket is rather small in comparison to my leather sling 2.5 x 3.5 inches fiber as opposed to 4x6 inches leather. On the other hand, the fiber socket seems to grip projectiles fairly securly in comparison to the leather socket. This allows me to throw some smaller projectiles fairly well and continues to hurl golf ball sized rocks fairly well too. It does balk at the larger tennis ball sized rocks. Now as to accuracy and hunting abillity, I do not feel that I have enough accuracy to even start hunting. I figure that when I can knock off soft drink cans 4 out of maybe 6 hurls, then I'll know that I am good enough to consider hunting. I need to start on another sling soon, and try to split the socket just like the Andean slings, I figure that will allow for larger projectiles. I also need to practice more. Holding that single tether down firmly would keep the spoon from flying off, I think this would still be best as a crew served weapon, one to sling and one to pull the pin. As I understand it ,the fustibal only took one swing to launch. To me that says fewer chances for the dangerous projectile to fall free or head in any direction but the one you want. I'll attach the one article I was able to find at a SCA site about the fustibal. So many things to try and so little time. --=====-1358866192==\_===== Content-Type: text/plain; name="The\_Staff\_Sling\_\_Guidelines\_for"; charset="us-ascii" Content-Disposition: attachment; filename="The\_Staff\_Sling\_\_Guidelines\_for"

## The Staff Sling: Guidelines for Construction and Use

**This article is intended as an introduction to a missile weapon which was extensively used from antiquity**

until the high middle ages, notably by the Carthaginian, Vandal, Roman, Byzantine and other armies of the continent. This weapon was called the fustibalus (in Latin). To the right may be seen an illustration from a manuscript in the Bodleian Library in Britain, which shows maritime combat with the fustibalus. It is also mentioned in the Codex Antlanticus of Leonardo da Vinci, who experimented with various forms of it as an exercise in martial engineering.

The Fustibalus was about one meter in length, and boasted a range of some 550 feet! Accuracy with this weapon comes only with practice, and its use among the romans was restricted to auxilliary troops for this reason. The trebuchet, a siege weapon much beloved by medieval engineers, was nothing more than an enormous staff sling that employed a counterweight for acheiving torque instead of arm and shoulder. The missiles launched were, in antiquity, referred to as glans. These were clay and/or lead pellets, oval in shape and generally flattened. They often had the names of enemies, pictures of scorpions and other martial graffiti inscribed or molded on them. Those samples remaining today are about 1 1/2 to 2 1/2 inches in length and 1/2 to 1 1/2 inches in width. These glans weigh around two ounces, though examples exist weighing up to five.

So how do I make one? Take a rattan stick about 30-40 inches long and make a leather 'pocket' as shown in the diagram. By securing one end some 6-8 inches from the tip (with the thonging), you'll set the range of your particular sling. Remember, you're going to lay a slightly flattened, never round, missile in this pocket and swing the staff 180 degrees. The point of release, and thus the range, will depend on the length of the thonging holding the pocket. Only trial and error will help you set your range. The other end of the pocket MUST slip off the tip of the rattan smoothly - it may be nessecary to smooth the place where it clears the end with some sandpaper. Always use tennis balls for SCA combat which have been slit on four of their sides. You could even attach red/yellow streamers to represent the clay incendiary grenades the Carthaginians threw from theirs. Of course, you'll need to duct tape before slitting. Hope to see you at the Siege!!!

Content-Type: text/plain; charset="us-ascii" Status: U X-Mozilla-Status: 0001 Just a note; The Kurds teach their kids to use a sling for small game. They use a thing "staff sling" to give the kids the right timing and arm motion. The only difference between the staff sling and a regular traditional sling is that one of the cords is replaced with a stick. The sticks are roughly oval in cross section and 2 to 3 feet long. Naturally they release the string and not the stick when they throw. I tried this method and it is really quite easy to use. Later I found out that Assyrians used it and some ancient seafaring nations used it because it wouldn't foul the rigging. There is basically no windup. It's used something like an atlatl and can be attached to a walking stick. Another thought. When I teach the sling in our advanced courses. I've learned that some folks can be accurate with a horizontal overhead swing, others take to the vertical swing which may be easier underhanded or overhanded. I let them try all of the positions and choose the one most comfortable for them. Up on the Cordelierra in Chile, the indians showed me how they teach their kids the overhead swing. They start with a short string.... about 1 foot long, until the kids learn the release points and coordination. Oddly the adults carry one of these short slings almost everywhere. The little slings don't have much range but they don't require a windup, can be used in brush and trees and will kill easily out to 20 yards or so. They're even good at the "fastdraw". Peace, Ron Hood Hoods Woods - <http://www.survival.com/~diogenes/> Get a giggle, Check us out! Ron Hood Ed.D.

Well now, maybe that would give us a use for those little sleeve throwers that I've seen available out there that are too small and light for accurate throwing. I had one for a while and found that it made a dandy light spear when attached to the end of a 4 foot shaft. I saw a set of three available for about \$20. That would make a base set of three for practice once set into the split end of a stick and glued and lashed into place. Also when I was a kid in Boy Scouts an Army Ranger told us to put a few of the glue on broadheads ment for cedar arrows in our survival kit so that we could improvise spears for hunting/defense. We loved that macho B.S. and dutifully added at least one to each kit(combined our resources since they came 6 to a set) I still think some of the larger broadheads ment for traditional archery would work out fine although you would probably have to taper your shaft carefully, or wind up with something that looked like a roman pylum.

James Keating's COMTECH (U.S.) martial newsletter, the Excellerator (XCLR8R), an eclectic self defense bulletin, arrived at the same time as I read the above message and Ed Sackett's mention of the Madden book, "The Art of Throwing Weapons" (on Matthew's "Thrower" website on his "Books" page, so I'll pass this complementary little column on, for what it's worth. BTW, COMTECH contact info and two of their weapons articles are also on Thrower's Whip and Chakra pages at Matthew's website:

#### SPEAR AND POLEARMS OF THE 90'S

"The Cold Steel Special Projects Division has delivered again. They have brought us the "king of weapons" in a classic form. Spears are just plain cool, and once you fiddle around with a good one for awhile, you start to see why the ancients valued them so much. I have a Cold Steel Boar spear and the Assegai. These are serious tools, perhaps the ultimate defensive device one could possess besides a gun. These beauties come with two handle lengths to suit your needs (basically long and short). If you want quality, but are on a budget, then give Cold Steel a call 1-800-255-4716.

Pat Crawfords survival staff/spear is another nice piece of work for those looking to spend a little more on their polearm. The spear head can be concealed in the body of the staff until needed. It quickly screws in and snubs down tightly, this is a thruster head. The nice part about Pat's piece is that you have stick, stick and dagger, dagger, staff and spear all in one! Pretty slick outfit for hikers and the

like. Call the Cutlery Shoppe: 1-800-231-1272, and tell 'em Keating sent ya. Remember gang, in today's world, one must not only be deadly in their personl defence, but resourceful as well. The unexpected tactic, weapon or boldfaced lie are as valid in your defence as a gun and the grenade. A bladesman without guile is dead. Look for a rad polearm/spear video training tape from Comtech in the near future. You'll see it first in the XCLR8R!!!"

javelins tended to have lighter heads as they are meant to be thrown longer distances than a true spear. I own one of the cold steel javelins and it seems about right to me. the head is a touch lighter than the medieval examples i have handled but, so is the shaft (at least the shaft is of a smaller diameter) I have not been hunting with mine but i have competed with it in several sca (society for creative anachronisms) competitions and it performed quite well even though it was being thrown into a wooden target, the head has not bent yet even with this kind of abuse. -ketil

Hi, just off the top of my head, from aerodynamics points of view, a spinning projectile (spin normal to the flight trajectory) actually help to reduce the orbital wobble of an irregularly shaped missile. The latter helps to reduce aerodynamics friction and orbital wobbles.

Please do correct me, I am a bit rusty on aerodynamics now.

Cheers and merry christmas, shirley

>THANKS RYAN LOEW 12 YEARS OLD mikeloew@execpc.com

Hi Ryan!

First- don't touch that hunk of aspen. It is too thick and too heavy to  
make a good boomerang. It is also not wide enough. Go find some aircraft  
grade birch plywood at a hobby store.

Here is a clip from the FAQ ([www.staff.uiuc.edu/~brazelto/boomerangfaq.html](http://www.staff.uiuc.edu/~brazelto/boomerangfaq.html)):

Although boomerangs may be made out of any of several plywoods, the  
material of choice is aircraft grade Finnish birch plywood between 4-6mm  
thick and 5-12 plies. Although maple, mahogany, ash and even pine may  
suffice, no wood gives better flexibility, workability, and strength than  
Finnish birch. Cheaper grade birch plywood (and sometimes even the good  
stuff) can usually be found in your local hobby shop. This wood is very  
usable for prototypes and kids' rangs. Rarely have I found more than 5-ply  
wood in 4-5mm at any hobby shop. The good stuff is available from a few  
places, only one of which worth mentioning. That is Anderson International  
Trading.

Anderson International Trading

1171 N. Tustin Ave.

Anaheim, CA 92807

USA

(714)771-6270

(800)454-6270

FAX (714)771-0508

Anderson gives discounts to USBA members.

Now for plans. Visit this site to get some easy plans:

<http://boomplans.montesquieu.u-bordeaux.fr/>

I would recommend the Pfeil for a first boom.

<http://boomplans.montesquieu.u-bordeaux.fr/anglais/desc/Pfeil.html>

However, please read the following clip from the FAQ before you make your first boomerang:

The best method for making your first boomerang is to copy a boomerang that works well for you. That's right; you have to buy (or borrow) a boomerang before you can make one. There are many people that I know who have tried to make a boomerang without ever having thrown and caught one successfully. This is preposterous! It is not reasonable to assume that you can make a boomerang that works if you don't know how boomerangs work in the first place. However, I have also known people to make a boomerang that works relatively well when following precise instructions from a source such as the book *\_Boomerang: How to Throw, Catch and Make It\_*, by Benjamin Ruhe and Eric Darnell.

That said, let's discuss what tools are necessary for your new hobby.

1. a band saw or scroll saw(for cutting out the general shape of your boomerang
2. a drum sander or belt sander or a rasp and wood file
3. sandpaper (several different grits)
4. water-resistant sealer like polyurethane or an acrylic

So find a boomerang that performs nicely, trace its outline onto your sheet of plywood (you should probably use plywood for your first booms, then on to other materials) and cut it out. Then the rest is just being a copy cat. Shape the boomerang just like your trusty model and take it out to the field for testing

BEFORE painting and sealing.

If this is your first attempt at making boomerangs, it might not perform quite like your "prototype". So some adjustments may be necessary. Inspect the two boomerangs carefully and note any differences no matter how insignificant they may seem to you. Reshape and try again.

Hope this helps.

That has been my impression of returning sticks. That's why I'm  
interested in information to the contrary. Ted Bailey and his associates  
have apparently measured and weighed some of the sticks in museums like  
the ones found in Tutankhamon's tomb and replicated them and found that  
there are many that return when thrown. As far as accounts I have read  
are like the account in "The Land and Wildlife of Australia" by David  
Bergamini (1964): "Crouching beside an oxbow lake in one of the half-dry  
river courses, a duck hunter would hurl his boomerang above a flight of  
oncoming birds. At the same time he would screech like a duck hawk.  
Tricked by his calls and by the shadow of the boomerang overhead, the  
ducks would dive low into nets staked out or held up by collaborating  
hunters farther down the billabong. In stead of falling into the water,  
the boomerang, meanwhile, would land at the feet of the thrower and be  
ready at hand for the next flight of ducks and the next cast." So, my  
impression has been that it was more of a distraction device. Tell me,  
do you have any experience taking game with a thrown stick in your  
survival trips? I have been out with one and taken many shots but have

not hit a living target yet, although I have been deadly at times on practice, stationery targets and have tested many non-returning throwers. Without a doubt I like the curved variety with beveled edges, convex on either side.

Hey, I think I'll post this to the rest of the THROWER community. Anybody have any thoughts or experience in what Andre and I have been discussing? ---Benjamin (benjamin@perigee.net)

Subject: Updated Boomerang Software

CC: THROWER@dfw.net, Primitive-Skills-Group@uqac.quebec.ca

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

If you have received this email message and you do not subscribe to the thrower, rang\_list or Primitive Skills email subscription services; and you do not want future notices about boomerang related products, tournaments, and other information, please send me an email message and I'll remove you from my email database. If you do have an interest in boomerangs, please read further.

This is just a short note to let boomerangers know that I spent several hours updating all the boomerang software disks. A complete list of all software can be found at the following URL:

<http://ic.net/~tbailey/Boomerang/Shareware.html>

Some of the software highlights include:

1: Three complete books about boomerangs with drawings, photographs, etc. These three books are out of print classics that are required reading for anyone who is interested in boomerangs. Every photograph and drawing from the original text is included. These books are available in MS Word 2 (readable with higher versions too) format for DOS/Windows and MS Word 5 (and above) format for Macintosh. Other word processing applications may be able to open these files as well, but I can't guarantee anything. The three boomerang books include:

Michael Hanson's Book: "The Boomerang Book"

John Mauro's Book: "An Introduction to Boomerangs"

Herb Smith's Book: "Boomerangs; Making and Throwing Them"

All three of these books have been replicated with the permission of the copyright owners and I have been granted a license to distribute these files to you as shareware. That means that your only charge is my fee to copy and mail it to you. You may not market these files commercially to others.

2: The boomerang databases have been updated as of 1 January 1997. Some of the more popular files include:

a comprehensive bibliography of boomerang literature

an updated listing of collectable boomerangs with a full description of physical characteristics and collectable value

two comprehensive databases of: USA (1700+) and Overseas (1300+) throwers. This includes everything from addresses to phone/fax/email. This is an excellent source of information for finding other throwers in your city/state/country and for organizing local boomerang throws. You may not use these files for commercial purposes.

Please don't ask for database files in Mac, DOS or WIN formats. These are operating systems, not applications. The available Mac/DOS/Win file formats are listed on the web page mentioned above. Most word processing, spreadsheet and database applications can read the generic tab-text format or can import files from one of the other formats listed. Word Processing and Spreadsheet applications have only limited sorting capability. A database program is preferred for using these files. The files were created using Macintosh MS Works 4.0 and then translated to the other formats.

There are a lot of other software goodies too. Sorry, but I cannot email these files to you, even if you are related or my best friend. You need to order them through the mail. If you live in the USA or Canada and want a printed copy of the software list mailed to you, send me your postal address by email. As a January special, current Boomerang News (paid through issue #33 and beyond) subscribers are entitled to receive their disks without a shipping charge. Orders received after 1 February 1997 will require shipping unless ordered with other boomerang products. You can subscribe to Boomerang News through the instructions on the web page: [http://ic.net/~tbailey/Boomerang\\_News.html](http://ic.net/~tbailey/Boomerang_News.html) New subscribers will receive a 10% discount coupon on Boomerang Man products.

Thanks for taking the time to read this. - Ted Bailey

The long running Rabbit Roundup (goes by something like that) is in south eastern Idaho too. Thousands of rabbits are thrown and clubbed at after they beat the brush for their enormous population. Traditional for yearly crop success. Any chance anyone has information on this? Seems like a fine place to bring your rabbit sticks.

Subject: body odor

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

I was looking through a Brigade Quartermasters catalog when I came upon an ad for "Odor-Stop" Long Lasting Deodorant. Supposidly researched secretly by the Russion Army. Only \$14.99. Stops odor 8-14 days!

Well..... the active ingredient is simply zinc oxide paste, available in any drug store for about \$1.50 a tube. The mechanism of action is simply to kill the odor causing bacteria that live in your skin pores. It's the same idea (and same active ingredient) as the cream (Desitin, I think) used for diaper rash in babies. I have used this method for many years and it does work with absolutely no side effects. Odor protection lasts for me up to three weeks in cold weather. If you want to try this, shower first before going to bed. Apply thoroughly to underarms (also works on feet provided odor is not a result of severe fungal infection). Wash off any excess in the morning. Some people I know have reported that several daily applications are necessary to get the effect going. After that, just use your nose to monitor the "pits" before showering to know when to reapply. I would be interested to know of anyone else's experience along these lines.

In the Idaho Pacific Northwest we have a nifty bush called the  
Thimbleberry (Rosaceae, *Rubus canadensis* L.). It pretty much ranges  
from Coast to Coast in North America. Grows together with Huckleberry.  
Thimbleberry leaves are shaped like oversized Maple leaves and though  
the tops are a little prickly, the broad undersides are quite soft and  
perfect as field-expedient toilet paper. I almost never use anything  
else on walkabout. Couple of leaves on a splurge.

Another "Made in Idaho" item of mention in this vein is the "U-Dig-IT.  
This is a well constructed folding handle stainless steel trowel with a  
heavy leather or Cordura sheath. Costs about \$15-\$18 and will last

forever. Advertised as "The Cadillac of Cat Hole Digging Implements." Standard issue for the US Forest Service. Doubles as a signaling mirror, fish scaler and as a firepit and encampment entrenching tool. One of my favorite "cutlery" friends. I've seen it sold in catalogs like Brigade Quartermaster and Boundary Waters. Really recommend this. Boise's gift to the world (if you don't count potatoes).

Turds..... Ahhh .....What a wonderful subject. As a matter of fact it's of  
my favorite. I find them quite amusing. After Ron got this message, I  
started thinking.....about turds and how much it really does suck when  
there's no toilet paper. Wiping with a flat rock is really interesting.

I can't count the times I've been walking on a trail and see a wad of toilet  
paper sticking up with a brown steamer attached to it just begging for my  
dog to munch it. First it makes me laugh, then it makes me angry.. So  
anyway, I looked up "toilet paper" in the "Leave No Trace" Outdoor Skills &  
Ethics book endorsed by the Forest Service and Department of Agriculture to  
find out what they think should be done about using toilet paper in the  
wilderness. Heres what it says exclamation points and everything:

"Toilet paper must be disposed of properly!..... The low-impact camper  
willing to go the extra mile might consider foregoing toilet paper  
altogether and using "natural" alternatives. Popular forms of natural  
toilet paper include aspen or sage leaves, stones, smooth sticks, fir cones  
and snow. Obviously some experimentation is necessary to make this practice  
work for you, but it is worth a try!"

Who wrote this book? Who the hell wipes their ass with a FIR CONE!! And can you imagine wiping with a wad of snow? These amusing images are imbedded in my mind. On the serious side though, if that's all you had, then you'd have to use it wouldn't you? (giggle)

Anyway, this brings me to another question for all you out there. What did the indians REALLY wipe with?

Gotta go ... Ron and I are going to make some maggot stew for dinner tonight. Mmmmm, Yummmm. Don't want to miss that! :)

And always remember ... a happy steamer is a Grogan.

I've heard that the use of dry corn cobs was a fairly popular choice before the advent of toilet paper. It may not have been used by the Natives but it was apparently practised by early settlers in North America. Once the kernels have been taken off and the cob allowed to dry, the remaining kernel husk, or what ever it's called, on the cob is fairly soft. I don't know how comfortable it would have been, but it sounds a lot more pleasant to use than a rock, smooth stick, or snow!

I think old timers soaked them in wood ash and water which caused them  
to swell. They then dried them and they would be soft and fluffy.

Hello All,

I have been reading this "turd" and "toilet paper" subject the last few days and never have I laughed so hard. It brings to mind another friend of mine who thought he was pretty good in the woods but really knew vary little. Seems he learned what he knew about the woods from watching old movies about mountain men. Well one day he he had to go, and in fact he did go. When the deed was done, he thought not having any toilet paper he would use some leaves to wipe with. He should have known more about his plants. It was Poison Oak. From that time on he used toilet paper.

Well I must say, I use toilet paper when in the woods and then I bury it at least a foot deep and away from any water. I'm not about to stick anything up there like a stone, a pine cone, a corn cob, or a stick. The vary thought of it makes me think pain, tenderness and deformity :-) All I can say to those that do use these other things to wipe with is that you are better woods folks than I :-) Keep them coming folks, I love this stuff.

I think Karen Hood got us going down this turd paper trail. So Karen,  
here's one for you  
HOW TO SHIT IN THE WOODS by Kathleen Meyer, Ten Speed Press, PO Box 7123,  
Berkeley, CA, 94707 ISBN 0-89815-319-0

A Sample of the TOC:

1. Anatomy of a Crap
2. Digging the Hole
3. When you Can't Dig a Hole
4. Trekker's Trots
5. For Women Only: How Not to Pee in Your Boots
6. What? No TP? or Doing Without

includes an appendix entitled "Definition of Shit"

Happy Reading

Heh, now this brought up memories that made me laugh! Although pretty much raised a city boy myself, my grandparents lived in the country and used kerosene lamps, a wood burning stove in the kitchen, outside water pump, and yes, the little shack out back for making water and steamers (did I get the turd, er, term, correct for that? ;^) There was never any toilet paper out there... but that's where I learned the meaning of "too hard and too slick", by personal experimentation with the occassional Sears and Roebuck catalog that was in there. It has to do with why the plain white pages were all getting ripped out and the glossy colored pages were left!

But, to the point, when the catalogs were all gone, there was always a couple of buckets of cobs. Most of the cobs were a reddish-brown color, but some were a creamy white. I asked my grandpa what the difference was and with a wink he told me, "First you use a brown one and then you use a white one to see if you need to use another brown one." I was mortified at the time, but have since seen packages of 2 brown and 1 white cob packaged with that saying, for sale in some cheesy tourist shops. Anyway, I'd pick an old cob over a pine cone any day!

Hello,

Mullein leaves (assuming you are talking of *Verbascum* spp.) have been used as a blushing agent in lieu of reddish makeup. When skin is rubbed with mullein, microscopic hairs actually abrade the skin, which makes it blush. If it makes face cheeks blush, maybe it will also make bum cheeks blush!

I have used sphagnum moss a couple of times but only the sanitized kind right of off a tree limb. it does have a tendency to leave some residual particles of plant matter behind. haha but it seems to get the job done and i believe it has medicinal values. does anyone know of any????

This is one of those a friend told a friend of mine stories so I don't know if it is true. Maybe someone else out there has heard of this. I guess durring some major war (Civil War I believe) troops ran out of sterile dressings. They used sphagnum moss and the wounds healed FASTER than with sterile dressings. Anybody else heard of this?

Jeff

I recollect that sphagnum was being harvested in Scotland during the Hitler war for possible use as a dressing. Dried sphagnum is highly absorbent and was intended for use as a dressing material instead of scarce cotton wool. A thick layer of sphagnum in a bed is a practical help in nocturnal enuresis.

Yes, as a matter of fact family oral history (backed up by two letters)  
indicates that this is what saved my relative's life (can't remeber the  
exact relationship, cousin or something like). Letter mentions how short  
of supplies and using the moss then 2nd letter mentions again and how he  
was now healing. This guy was shot at the Wilderness.

Not sure if this counts, but at archaeological sites in the arctic we would wrap organic artifacts in sphagnum moss that grew in the damp areas around ponds (though we were told by botanists that it was not \*technically\* sphagnum, but a relative). This kept the artifacts moist because drying too quickly can cause cracking and damage. It was also a cheap (free, actually) packing material, did a good job of protecting the artifacts in transport AND was supposed to prohibit the growth of

fungus and bacteria. Whether that was an attribute of real sphagnum, our faux-sphagnum, or our imaginations I can't say.

Cheers,  
Tim

I've always been taught that if you must use toilet paper in the woods, always take a trowel or small shovel, and bury it at least one foot deep, and/or cover it with a rock. Also crap far away from all water sources. I believe that most primitives used their hands and then washed afterwards or a combination of various barks and or leaves. It is still an insult in some societies to touch someone with which ever hand was traditionally used for wiping(I admit that I read this in an old airforce survival manual and cannot find it just now)

been doing this for years, but, now can't on military  
reservations. Too much of it buried here and there and we have to use  
the porta potties (jumpin' johns, creaky crappers, steamer shacks, mini  
hotels, etc.. ;) you get the picture). However, if it will wipe, is not  
going to give me a rash (probably), is within reach (with a little  
effort) and can be buried, I have used it. To be honest primitive didn't  
matter (I guess that is my "primitive" instinct).

Seriously, we bury it as much to keep it from being discovered as to  
protect the environment. A crap cache I guess!

Great thread of actual use to me. I really have enjoyed it but never can

find a sapling to bend over and sit on at just the right time.

Karen Hood asked:

> Anyway, this brings me to another question for all you out there. What did  
> the indians REALLY wipe with?

I love the net: you can discuss anything, even hemorrhoids...

Here are some answers:

The easiest and best way to wipe your bum out there (in my humble opinion) is to grab the base of a small leafy sapling and drag your hand up along it. This leaves you with a huge wad of leaves in your hand which you can use to do the job. There are very few leaves in the wilderness which are large enough or strong enough to do the job alone!

The problem is that when you use the one leaf method, the finger always ends up besides or through the leaf. Then you try to shake off the "merde" and accidentally hit your finger on a protuding stump. Ouch! and the finger automatically comes to your mouth for relief...

On the serious side, the huge wad of leaves does work very well, and even in the winter, there are always some types of trees (such as beech -Fagus grandifolia) on which dried leaves persist. Don't forget, it

doesn't matter how small the leaves are, as long as you've got LOTS of them.

Failing that, cattail heads will work if they are still solid enough not to fall apart. Bundles of grass work but leave little bits stuck as "willnots" (Will not want to be removed from there). Same problem with moss, it works but you end up with willnots. Birchbark is no good, it's too stiff, fingers go through it, and millions of willnots, especially if the white layer is used.

In Africa, the standard way of the Hausa people I visited is to use a long thin millet stalk, stick it between the legs, hold one end in each hand, and turn slowly while pulling back. This technique works with cattail stalks and other plant stalks. If you have a knife, you can whittle a smooth long stick also. Round smooth rocks from river beds, especially oblong ones, are pretty good. I've done all of this many many times and it works well.

I've also used snow, but not loose snow. Make an oblong snowball first. Usually, I use leaves, grass or stick methods for first wipe, and snow for the final wipe.

In remote areas in summer, my second wipe is always with water at the lake's edge. Then, with wet hands, I go roll them around in the cooled off ashes from the fire (that's where soap comes from, remember), and come back to the water's edge for final cleaning.

On a trip to India, I noticed that all poor people would wipe their bums with their left hand and water this way, then use soap for washing. The worst insult made to thieves in the past was to cut off their right hand, forcing them to eat and wipe with the same hand.

Of course, when animal skins were available, especially rabbit, that was certainly used also, maybe even washed and dried for the purpose. I know rabbit fur was used as a sanitary pad for indian women. (They also used finely tanned buckskin tubes filled with sphagnum moss for this purpose.) I obviously have not tried this.

I am convinced that the majority of primitive people used a first wipe with, in order of preference, leaves, smooth sticks, rocks, the second wipe being with water or snow. Without the second wipe, your brown spot turns red mighty quick.

While on this subject, a green tree about 3 inches in diameter, bent over, makes a great seat. After the job is done, the seat flies back up into shape, waiting for the next customer. Another very important technique is to place your heels on a piece of wood 2 inches high. Try it. It is infinitely easier to squat that way.

When burying your scat, it is better to do it not too deep, stay within the organic soil for faster decomposition. Then again, just tossing an old log or rock on top is good enough in remote regions.

I know this was a shitty post,

Have a good dump.

Well, didn't the truly primitive diet make for easier to clean butts? So  
that lingering material was probably not too serious a problem.

I've read where studies indicate that the crude fiber diets would often  
pass thru the gut in less than 30 min.

On the other hand, our modern,refined foods stay with us much too long.

>I've read where studies indicate that the crude fiber diets would often  
>pass thru the gut in less than 30 min.  
>  
>On the other hand, our modern,refined foods stay with us much too long.

In addition to the "smudge factor" of modern foods over native foods, the issue of butt hair needs to be considered since clingers need a rope to hold. Now, can any of you gifted researchers answer the question "Does a Caucasion butt have a higher hair density than a native american butt?" and "Did hair density result in a higher cling ratio per cubic Cm of steam?" Gender differences may give us a clue. A trusted ass-ociate of mine conducted a "cling test". Her fuzz less ness had a very low clinger ratio. In fact smudging was the only difficulty she reported.

One other thing. Some years ago I was experimenting with Cattails as food. When the tops were past their prime but boiled thouroughly, they could be eaten, but not digested. The result I discovered was a feeling of fullness long after the meal. Eventually, after a complicated journey, the material had to re-emerge. Just before it did there was a period of profound gas discharges. Had I been in the city it most certainly would have annoyed the neighbors. Finally they jumped free, fast! There resting on the earth was what looked like a cylindrical pillow, a "self wiping" grogan if you will. Tho' it could have been broken up and dried for use as insulation, I decided to end the experiment.

Peace

My personal favorite is the lichen that grows in spruce and fir trees. I am not sure what it is called. In fact I have been trying to find out it's name for quite some time. Out west it is called Old Man's Beard or Usnea. I don't know the scientific name or even if it is the same stuff for that matter.

Anyone please correct me if I'm wrong but I think there are two kinds; one is light colored and one is dark. (sometimes they grow together)  
Your right, out west we call it old mans beard, Their scientific names are Usnea and Alecatoria but not sure which one is which. Has several uses; medicinal, edible and utilitarian (aside from your suggested use which I am going to try).

Another obvious wipe I use that I haven't seen posted yet is; Spruce boughs. (they rank right up there with Pine cones and corn cobs) Actually this "directional" wipe does work not too bad as you can 2 hand (one in front and one behind) and draw them through, they feel quite soft. Biggest disadvantage is some of the needles fall off into your underwear and you get "needled" periodically through the day. If you want to be enviro (we all do) and if the branches are low enough you can leave them attached to the tree. (Be careful where you collect your needles for your spruce needle tea or you may be in for a nice hot "steamer" cup of tea. Gulp!)

Quick question: from the postings I think this is also known as Squaw's Hair? The dark one, anyway, if there are actually two kinds and not just one that is drier than the other? I've often used this as tinder, along with the dead small branches found close in on the trunk and usually dry even in the most disparaging downpour, due to the tree's upper limbs and foliage.

Bill B.

P.S. I grew up calling these small (usually 1/4" dia. or smaller) twigs Squaw Wood, because of the Squaw Hair usually being found in the same spot.

I want to second that, Par. Spagnum is without a doubt the best I have  
found, and luckily I live in an area that has it in abundance. I'm  
fairly certain that spagnum has anticeptic and germicidal properties  
also, which make it a clear favorite. As one friend of mine is fond of  
saying, "spagnum for your spincter!" (ha, ha!)

Mark

I have tried sphagnum only once and it totally turned me off. I just

don't like the fact that it is wet and cold. Do you guys use it wet right off the ground or do you process it in any way. I have only used it we right off the ground. I don't much like it.

Jeff

I process it when I can. It's a little like blow drying....The best  
technique for drying sphagnum that I know.

Eat two pounds of beans, six ounces of spinach, two eggs and a chili dog.  
Wait two hours. When the urge hits, back up to the sphagnum and let 'er rip.  
The hot wind will blow all loose material and moisture into low earth orbit.  
Tuck in the resulting loose tissue, and apply Prep "H". As an additional  
benefit, there will be no hair, no clingers and no little field monkeys  
dropping from that cheeky speaker for some time.

A word of caution, the above recipe has been deemed a class one explosive.  
Do not attempt this near open flame!

Regarding eating cattails past their prime. I assume you mean they have turned to the brown, full of fluff, seed pod. If this is the case, you may want to try this. The Paiute eat cattail seeds. A friend of mine and I were scratching our heads about how they separated the seeds from so much fluff. Finally we just lit a pile of fluff which of course disappeared with a \*poof\* and continued adding a little at a time until what was left was some nice toasty seeds. Tasty but tiny.

Karen,

FIR CONES are remarkably SOFT--as long as you wipe \*with\* the scales.

Also...snow is not too bad! REALLY!!! Sometimes there is nothing else to reach for here in the north (Montana).

For lack of anything at all, you can always use "ranger wipe". With ranger wipe you wipe twice. First you wipe your butt, then you wipe your finger. It is for this reason that in many undeveloped countries the people customarily eat with only one hand--the other one!

If you "wipe twice" then be sure to sterilize your hands afterwards by vigorously rubbing with aromatic/antiseptic herbs like sage, juniper, or yarrow. Just about any highly aromatic plant will have antiseptic properties. As long as you can identify the most dangerous plants in your region, then you can safely use any others with aromatic properties.

It can be used as is, but what I generally do is grab a handful, squeeze out as much water as I can, and then use it. If I was in a long term camp (more than overnight, at the least) I might be bothered to dry some inside my shelter or on a stick near the fire. Oh, and do make sure to pick out at least \*most\* of the pine needles that is mixed up with the moss. Makes good field dressings, if nothing else.

Related question: I am told that women can use wads of (washed and dried) sphagnum as a sanitary napkin during their period. Anyone who has actually used this? I sometimes get questions when I teach courses, and being male it is all out of books for me, with no oppourtunities to experiment.

Usnea or Alectoria, I don't know Par. I've never even heard of them.  
I live in Western WASHINGTON, USA some places around are like swamps.  
The moss I'm referring to usually grow on tree limbs near streams and  
other bodies of water, and is somewhat stringy, would probably make good  
tinder for fires, and is green with a little yellow.

Please advice me on this, although it was very necc. to use this moss  
when i did, I don't want to wipe with some poisonous moss stuff.:)

Hard to tell from your description, but I doubt it's sphagnum, which is  
the bogforming moss of the northern forests. The color fits, though.  
Anyone familiar with the area and can help out on the possible ID?

/Par

Right off the "ground" (or bog to be more precise) for me. The wet and cold part doesn't seem to matter once I'm out there long enough to need to use the stuff.

I've heard of it being used to dress and pack wounds, although I can't say I've tried it. The Indegenous folks in this area used sphagnum to pack baby diapers. It absorbes moisture better than most sponges I've seen.

Another non-medicinal use is for insulating shelters. It's especially effective as an insulator after it's dry, though. I have found this to be extremely useful, especially in regions like mine where ground debri of any quality is scarce or non-existant at certain times of the year.

I have a wolf (coyote?) skin diaper made to use moss as the absorbent. I  
have pictures of me wearing it. Can I vouch for it's effectiveness or  
comfort? No way! But I can say that I was cute!

Subject: Eating Insects

Content-Transfer-Encoding: 7bit

Content-Type: text/plain; charset=us-ascii

Status: U

X-Mozilla-Status: 0001

I can only speak practically about insects in the U.S. however, it is my experience and also from things I have read that any insect is edible. Priority-wise you would want to avoid insects with poison and stingers, however, there are ways to prepare even these, similar to eating venomous snakes, remove the poisonous parts, then prepare the rest of the insect. Of, course this means having a knowledge of where the poisonous insects poison sacs are located. You also want to remove all parts that would hang in your throat, like legs and wings. It is also best to remove the head in most cases. All wild meat should be cooked thoroughly, for wild animals contain parasites that can get into your system, this includes insects, even small ones. Insects may be roasted and ground to a powder and mixed in a stew with other edibles. This is more palatable in most cases. This is also practical whenever you have several small things to eat, to make a stew and drink the broth and whatever is cooked in it. In some cases you can even strain out the solids and drink the broth for nutritional value. Most insects are high in nutritional content, like grasshoppers. Grubs are high in fat and nutrition.

One thing to keep in mind in hunting any animal you are going to eat is to never expend more energy in capturing it than it is going to give back to you upon consumption. Observe when insects are least active, if they are a type of insect that is particularly active, like a

grasshopper. Grasshoppers crawl to the top of grass blades during the night and become very dormant and still, They are most easily captured in the early morning, while still dormant and smacked with a twig and gathered into a basket or pocket. I have read that Indians would drive the the grasshoppers across a field to another group of Indians waiting with dried grass in a row across a field that they would light and roast them on the spot. I have not trested this, o, I don't know how practical it would be or if it even works. It could be heresay.

Aparently insects have been adding nutrition to our diets for quite some time. It wasn't unusual for hard tack and salt beef to get wormy, that is get maggots and other larva and men would eat it, because it was all they had. I've eaten ants , tart. Accepted technique for eating any insect is to toss them in a basket with coals from your fire then remove legs and wings and eat the body. The larger tarantulas aparently taste much like crab. To eat them you need to tie the legs back and then toss them onto a bed of coals. Make sure you suck or split all the meat out of the legs. I also hear that some people dry the insects, pull off the legs and wings and then grind them up and use them as an additive to soups. I've read that mayflies were an important part of the diet for Indians in areas where they have large swarms of them.

well,

i'm supposed to camp with a friend of mine from south louisanna this weekend. he says he is gwine-a teach me how to eat dem insects. his theory is that they are very plentiful, and that they require a minimum of energy expenditure to catch. he says " you would be amazed at the food avaiable in a rotting log -- look at dem bears, dey eaten grubs"

now from my limited reading on the matter, most insects and such are ok to eat, expect for the parsites, etc. that they might be hosting. So the question becomes .. if one cooks-em, can he eat with gusto, without worry about ill effects? what can't you eat in the way of grubs and insects?

now if my buddy is popping these little fellows in raw, do I do likewise, or be a woosy and say naw i got a cook-em first?

in a prolonged low light longterm survival situations, grubs, fungus et alia, might be a food solution. photosynthesis will be zip, but you will have a plenty of decaying plant matter.

what say ??

Mammals have parasites that can live in other mammals.

But do insects have parasites that can live in us?

Everything about their internals -- respiration, circulation, digestion --  
is completely different. I wouldn't eat a tick or mosquito that sucks  
blood, but other than that...

Critters like insects are both nutritious and delicious. They generally taste best cooked--roast or fry grubs, for instance. But unless you find them near fecal or polluted material, it is generally fine to eat most grubs and many other insects raw. Whenever I get hungry on a trail I kick open a rotting log and pop a few in my mouth for energy. Slimy yet satisfying.

Malaria in mosquitoes. Bubonic plague in fleas. Lyme disease in ticks. I have also had the experience of crushing a cricket and finding it full of tapeworms (there's a stimulus for your gorge!).

And fleas can also carry lice which have their own set of parasites which can call humans home. Kind of a two-for-one bug!

It is my understanding that All animals no matter how small, including insects have parasites. And, though, many eat them raw with no ill effects, it is safest to cook well all wild meat. If there are animals of any type that don't have parasites that anyone knows of please speak up, I'd like to know.

Here's a recipe from the late 60's "Last Whole Earth Catalog.

.....

"Re: Recipes for eating insects

This recipe comes from parts of Asia and Africa. Insert fried peanuts into cricket's abdomen (preferably cleaned). These prepared crickets are then fried. They are supposedly very tasty to those whose palate accepts them.

James Do (J.D.)"

The same source quotes the June 20, 1970 (vol.26, no.6) issue of Science Digest for another recipe that looks like it would adapt itself to a variety of insects.

- 1 pint termites
- 1 tablespoon vegetable oil
- 1/2 teaspoon salt

Remove termite wings, if any. Spread termites on stone to dry in sun. Pour oil in pan and spread dried termites on it. Toast over hot coals until almost crisp. Sprinkle with salt. "It helps the flavor, say those that have tried the recipe, if you eat the termites in handfuls." Science Digest credits the Bantu's with this recipe and reminds readers that there is "lots of vitamin B" in termites -

Termites aren't all the plentiful in parts of the U.S., but I suppose that the recipe would be just fine for ants."

Frank Walsh

I wonder if the formic acid content of ants would present any hazard if they are eaten in quantity. Andr ? You said ants are tart. The acid?

The current edition of "The Millennium Whole Earth Catalog" (pg. 46) lists:

The Food Insect Newsletter  
University of Wisconsin,  
Dept. of Entomology,  
1630 Linden Drive  
Madison, WI 93706

"Unique. Why it's harder to find chocolate-covered ants, and which big bottomed species are gourmet. Thumbs up to pupae puffs and a guide to the best restaurants. Love it and eat it. - PW (Peter Warshall)"

There's a website for The Millennium Whole Earth Catalog these days:

<https://www.well.net/mwec/mwec.toc.html>

Just a few thoughts....

>This recipe comes from parts of Asia and Africa. Insert fried peanuts  
>into cricket's abdomen (preferably cleaned). These prepared crickets  
>are then fried. They are supposedly very tasty to those whose palate  
>accepts them.

> James Do (J.D.)"

One recipe I learned to enjoy..... The montegnards would catch, crickets  
put them in a container which had a 2 inch strip of oil painted on the  
inside. The oil kept the little buggers :>) inside the jar. The little guys  
would hang out inside the jar for about 24 hours. This gave them a chance to  
empty their intestinal tracts (the cause of some bitterness in the flavor).  
After they were "clean" they were dumped into a cloth bag which was then  
hung by a fire to dry (cook slowly) or left in the pot and heated in situ on  
a slow fire. When dried they were munched as a tasty snack or used in rice  
meals. Grass hoppers are prepared in the same way but it is best to pull the  
legs off before the feast.

In any case, either bug (or most bugs) can be crushed and added to stews.  
This disguises the appearance and reduces the spew factor.

> Termites aren't all the plentiful in parts of the U.S., but I suppose  
> that the recipe would be just fine for ants."

> Frank Walsh

Ants are, for the most, part one of the best bug feasts. The formic acid  
pretty much disappears when they are boiled. Black ants eaten raw have a  
semi sweet flavor. Sorta like crunchy raw sugar with legs. We use them to  
sweeten ephedra tea.

Bees and wasps are OK eaten after a good boiling. The poison is basically a  
protein which disassembles at boiling temperatures. The stinger softens.  
Pounding them before boiling is effective. Bee and Wasp Larvae are delicious!

One of the most dangerous insects is in the cantharidin family (blister  
beetles). I doubt that you will run into those unless you pop over to the  
Mediterranean just to munch bug. There are of course many cautions.....  
Just a note. Beetles amount to about 40% of the known insects. The larvae of  
many beetles are very high in fat and protein and make great snacks.

When in doubt about a bug do the insect safety test. And follow these time tested rules.

Always try to cook insects.

Never eat bugs you find dead.

Don't eat ones that bite back!

If it smells really bad, don't eat it!

One last thought..... If you have a strong stomach,,, or at least a clear spew zone for a technicolor yawn..... try maggots. Road kills are often infested with them. Gather a handfull or two, drop your prize into an old sock and rinse in cold clear water a couple of times, then boil. After about five minutes toss in a bullion cube. When it is finished dissolving, settle back to a fine hot stew of what looks like brown rice. It is really a fine meal.

Graeme Newman wrote "The Down Under Cookbook" more than 10 years ago. I met him in Albany New York in 1988 and traded him a boomerang for one of his cookbooks. One of the recipes is as follows. There may be some errors because I OCR'd with my scanner - Ted Bailey

#### WITCHETY GRUBS

Witchety grubs (from the Aboriginal witjute, the name of roots in which the grubs are often found) are various larvae that feed in the wood of eucalyptus trees, most often between the bark and the trunk. They are about 1 to 2.5 inches long, with a fat creamy body about the width of a man's thumb, and stumpy legs. The Australian Aborigines who live in the Outback are said to consider them a delicacy. As with most food taken by the Aborigines in the Outback, they eat their witchety grubs raw. I have never tried them prepared in that way. I recommend them cooked as follows, Outback style.

witchety grubs  
an old piece of metal  
salt and pepper to taste  
a little cooking oil (optional)  
yams

So you're stuck in the Outback without anything except a little salt and pepper! The Outback is desolate often without vegetation, but one is sure to find somewhere a scrap piece of metal left from some failed effort to drive an enormous distance, or maybe from a Mad Maz movie set. Scrub the metal clean, hopefully in a little sand and water from a nearby trickling creek. Prepare a fast, trench fire and place the metal across the top. Immediately place yams in coals beside the fire. After about 2 an hour, when the hot plate is quite hot, drop the witchety grubs down and rapidly roll across the metal plate. Keep rolling until they are browned all over. Remove from heat, allow to cool. Remove ya.ms from coals. Break open yams and serve each yam with a witchety grub nestled in the middle.

On a dare, I once ate a witchety grub cooked according to this recipe. It tasted quite delicious, somewhere between roast pork and chicken, and it stayed down too. But I have to admit that I haven't eaten one since.

Grub is a word used by Australians to refer to any larvae found in the garden and elsewhere. When I have asked my American friends what a grub is, they invariably reply that it is a "freeloader" and rarely relate the word to insects (real insects that is). Australians have their own word for a freeloader: a bludger.

So...let me see, do you boil black ants before you put them in Ephedra tea or does RAW mean they're live, freshly squashed or dried? Are they 'sweetly' doing the backstroke in their steaming teacups? Is there a baggy full of sweet and crunchy black ants lying around over there by the tea strainer? Inquiring minds want to know.

Interesting recipes - I've been enjoying your website Ron and Karen. Thanks to John Waltz, Andr  Bourbeau, Benjamin Pressley and all the others for their recipes as well .

Ron, apparently you have tried this! I wonder if you tried to clean  
out the maggots intestines before eating them? Or is boiling them  
to kill whatever germs might be in their little guts from what they  
were eating sufficient? Seems like those maggots must have a bunch  
or rotten meat in their little intestines.

> When in doubt about a bug do the insect safety test. And follow

I guess I wasn't on the list when the insect safety test was explained...  
Will the archives go back to the beginning of the list?

Thanks,

John Wiedenheft

>Ron, apparently you have tried this! I wonder if you tried to clean  
>out the maggots intestines before eating them? .

All I ever do is boil them, Thouroughly. Sometimes I get a little white foam on the top of the boiling water, This stuff has an interesting odor. If you want to taste it, It's good to have a cold.....Either way, the flavor of the foam isn't bad tho' I prefer to skim it off. The dogs LOVE it!

Usually the maggots I collect are from range cattle who've died over the winter. In addition to the maggots I often find the carcass's contain good material for other uses. The stiff skin can be softened and used, there are the tendons, hooves and even some aged beef (occasionally).

>> When in doubt about a bug do the insect safety test. And follow  
>  
>I guess I wasn't on the list when the insect safety test was explained...  
>Will the archives go back to the beginning of the list?

I have no idea if it was posted. I came into the group in the middle of an insect discussion and sorta assumed that the process had been reported. If not, I'll be happy to put it up.

Peace,  
Ron Hood

>or rotten meat in their little intestines.  
Well, I have a friend/customer in Georgia who markets a video tape EATING  
CROW. He explains all about how to hunt crows and eat them.

I recall asking about the safety of eating crows(I was putting them in  
the same class as buzzards and other carion eaters). He informed me that  
nearly 100% of the crows he had killed were full of grain and insects not  
"road kill".

Perhaps maggots and other such life forms can have safe to eat guts...and  
I guesss if you gotta, you gotta....BTW...wife is making sourdough  
pancakes and she's just called me to breakfast....

... reminds me of something the Danish explorer Knud Rasmussen wrote  
about his stay with the Netsilik Inuit:

"Right alongside the spot where we pitched our camp we found an old  
cache of caribou meat -- two years old I was told. We cleared the  
stones away and fed the dogs, for it is law in this country that as soon  
as a cache is more than a winter and a summer old, it falls to the one  
who has use for it. The meat was green with age, and when we made a cut  
in it, it was like the bursting of a boil, so full of great white  
maggots was it. To my horror my companions scooped out handfuls of the  
crawling things and ate them with evident relish. I criticised their  
taste, but they laughed at me and said, not illogically:

"'You yourself like caribou meat, and what are these maggots but live  
caribou meat? They taste just the same as the meat and are refreshing  
to the mouth."

I guess if you think of it that way, then they are just processed meat.  
Sort of like tiny, wriggling hot dogs. Maybe thats what he means by  
eating them with 'relish' :)

Cheers,  
Tim

I'm sure most of you have had this experience. You are telling someone about your interest in primitive skills and of the excitement and thrill of 'survival' living, when a concerned look comes over the face of your listener. "You don't eat B-U-G-S, do you?", they respond. The truth is that this is an area in which I have very little knowledge. Does anyone have any information (books, links, etc.) pertaining to the harvesting and preparation of insects as a food source? Many thanks in advance.

Jon Harshbarger

I, too, would like to know about bugs as food.  
I have dozens of books on most every other aspect of wilderness living,  
but nobody wants to talk about bugs as food, not even my US military  
survival manuals.

You may wish to inquire with Andre how to access a thread that was started on this already. I also recommend "The Food Insects Newsletter" available for only \$5 from the following address:  
Florence V. Dunkel, Ph.D., Associate Professor, Editor, Dept. of Entomology, Room 324, Leon Johnson Hall, Montana State University, Bozeman, MT 59717-0302, USA.

This reminds me of something I saw on PBS in a discussion of scanning electron microscope photography. It went something like this:  
Little fleas have smaller fleas upon their backs to bite'em  
and smaller ones have smaller still, so on ad infinitum.

It is my understanding that All animals no matter how small, including insects have parasites. And, though, many eat them raw with no ill effects, it is safest to cook well all wild meat. If there are animals of any type that don't have parasites that anyone knows of please speak up, I'd like to know.

2.19.4 Which lemon grass do you have?

-----

>>A friend told me he was buying small lemon grass plants to put in his  
garden to help keep away bugs.  
>>Has anyone ever heard of lemon grass as a bug (I assume he meant, gnats,  
etc.) deterrent?  
>Perhaps there is a connection to citronella?

>From herblady@super.zippo.com (Rastapoodle):  
Boy, are we confused here folks, but it is a common mistake. Here's the  
story: Lemongrass, a delightful plant, and it's close cousin, Citronella  
have many wonderful properties, releasing their scent into the air not  
being one of them.

Lemongrass is wonderful to eat, Citronella is \*not\*. They look similar,  
so

be careful what you buy. Citronella is distilled to extract its oil, which is used in insect repellent candles, burning coils, etc.

Very interestingly, a Dutch plant scientist did some genetic engineering and spliced the oil gene of the Citronella into a Pelargonium (scented geranium) plant. The resultant plant looks like a scented geranium, but gives off the fragrance of Citronella (and rose, the original scent of the geranium) to the air with just a breeze or a kiss from the sun.

The hybrid is called Citrosa, and it is patented (you can't make cuttings for sale). A fully grown Citrosa (about 4 x 4 feet here in Miami) is supposed to protect a 100 sq. ft area from mosquitoes.

Hope this clears up any confusion.

Anya

PS I have planted my Citrosa among my Lemongrass for an ironic statement.

-----

>I would like to know if it is worth while to grow citronella plants with the idea that I can make citronella candles. I don't believe I have seen these plants in any of my order catalogs and none of my gardening books tell how you get the citronella out of the plants.

From: adgrant@water.waterw.com (Andrew Grant):

Commercially the oil is extracted by steam distillation using old extracted

plants as fuel. I doubt that you want to get that elaborate. I have never

tried it but I suspect that the plants could be chopped up and extracted with a solvent like alcohol or toluene. Of course you would then have to boil off the solvent. If you do contemplate this, know that the % oil in the plant is low (I have forgotten the number) so your yield will be

low.

Incidentally the notion that citronella discourages mosquitoes is not well supported by my experience. I have seen mosquito larvae in rain water on top of drums of citronella oil with oil droplets in the water!!!

>I'd appreciate any information or leads you could give me on extracting  
>oil from cymbopogon plants.  
>  
>Thank you very much.

Sorry to be so slow about replying but I don't check my email every day.

I worked with citronella oil in the 1960's. My job was to develop or improve processes for the isolation of individual components and for the conversion of those components into other chemicals such as L-menthol or dimethyl octanol. My interest in the extraction of the oil was part curiosity and part a desire to try to understand some of the variations in

the quality of the oil as imported into the United States. I have long since retired and no longer have access to the literature. All of which is by way of saying that I do not know a great deal about the extraction beyond what you have probably already read.

My understanding was that growing cypobogon and extracting citronella oil was basically what we would call a cottage industry. That is it was grown in very small plots. The individual farmers set up small crude stills and steam distilled the oil from the chopped up plants. The vegetable residue from the still was sun dried and used as fuel for the next distillation batch. The individual batches were sold to collecting stations and there bulked together and drummed up for export. An old reference tha covers some of this history is in "The Terpenes" vol. 1 (university Press, Cambridge 1947) the authors were Simonsen and Owen.

A good source of additional history references would be chemical abstracts. I don't know the CAS number for citronella oil itself, but you can get that easily enough. You might also want to check CAS for the individual components:

|             |          |
|-------------|----------|
| Citronellal | 106-23-0 |
| Citronellol | 106-22-9 |
| Geraniol    | 106-24-1 |

I do hope this is helpful.

My grandma also used cucumber peelings to repel ants. I helped her  
lay out the peelings as a child. They worked great for about 24  
hours--then the ants started eathing them!

Content-Type: text/plain; charset="us-ascii"

Status: U

X-Mozilla-Status: 0001

Just wondering about any "natural" repellents for ants, and other ground insects.

My personal interest is that I live in a ninth floor apartment in Honolulu, and am repeatedly plagued by ants, a type small enough to crawl through the holes in window screens. I started out by buying some raid brand ant hotel kine traps, but this isn't working in the long term. Not interested in contributing to the already large amount of wasted matter in every dumpsite, so looking for a more reasonable solution.

Thanks for any help in advance.

Zachary

Zach,

Grind up black pepper and crush it into powder. Spread it where they  
are seen, esp. on their trails in and out - bottom of doors, along  
windows, etc. With severe infestation, you might want to run some along  
rghe outside of your hacienda. Takes about a day or two, but the black  
ants will go away. Have faith. They track it around on their feet and  
they don't like it. Breaks their scent trail, I figure. Maybe cayenne  
would work too, but I haven't tried it - might be fun to try that on

"red" ants sometime. Just powdered pepper - you don't need anything else. Clean it up in a week or two. They usually don't come back, anytime soon.

well ive read that diatomacious earth might work.. sharp edges  
on the diatoms scratch the bugs and they dehydrate. havent tried it  
so can't say for sure.

another thing you might try:

nicotine is a good killer .. boil up a batch of chewing tobacco.

im sure there must b a few things they dont like the smell of and  
will not cross. ammonia ? camphor ? capsicum ?

maybe a plant in your neighborhood that you never see any ants on ?

maybe try crushing a bunch of them and making a line .. maybe they  
can take a hint ?

> maybe a plant in your neighborhood that you never see any ants on ?

Excellent idea, but you might want to check and see what bugs this plant  
DOES have. Hawaii has centipedes and millipedes, I understand? So you  
wouldn't want a plant that ants disliked but was like honey to the 'pedes.

> maybe try crushing a bunch of them and making a line .. maybe they  
> can take a hint ?

Some insects actually will take this hint. One thing you can do is catch  
a whole bunch of bugs and crush and boil them. Spray or paint the mixture  
around. Doesn't always work, but sometimes it works wonderfully.

Bill B.

I remember my mother always used cucumber peels against ants. Don't know what's behind this, but it seemed to work.

While on the subject of repeling ants, how about ants as repellent?

Has anyone ever read or heard that you can "stir up" red ants and they'll emit a clear odorless substance (supposedly they spit it) that can be used for insect repellent? Is there any truth to this?

The land of bad bugs

Am told by reliable sources and have experienced it some that eating of  
wild food tends to make you unappetizing to insects (and uptown girls).  
The more wild you eat the greater effect. Also a note from Chinese  
medicine, most wild foods are considered tonic, which produces an

alkalizing effect on the body both promoting health and making natural living more tolerable.

A bit off the topic but I heard from an entomologist that insect "pests" are not usually a problem in places where they came from; for example, Japanese beetles are not a problem in Japan because the predators are there to keep them in balance. Integrated pest management focuses on creating balance, something we as primskillers should strive to achieve in our local environments. The old caretaker attitude.

>From what I can gather from Nessmuk's book, his combination of pinetar  
and oils was not really an insect repellent, but more of an insect  
barrier. We could go deeper into this subject, but insect barriers were  
where the old saying arose: "don't wash or you'll be bitten alive".

This is

> fascinating to me but the best I have found is a combination of liberal  
> applications of DEET

Alternatives to DEET and the way DEET functions is another subject of interest. Some researchers have found other products, such as Ethanol, which might affect mosquito sensors in the same way as DEET.

and ingestion of above average quantities of vitamin  
> B (various).

I still haven't found any scientific evidence of this, and would love this subject to be pursued further also.

Where I live we also have chiggers and ticks as major as  
> major pests as well as mosquitos (much diminished since the early '60s)  
> and various flies.

Still another subject, because you defend from black flies and from mosquitos and from deer flies in very different ways.

>  
> I see this topic as having 3 major threads:  
> 1. Topically applied solutions for use as repellants.  
> 2. Dietary supplements.  
> 3. Botanical environmental additives (hanging of plants in you immediate  
> area to discourage pest activity). Marigolds?

I think we could go even more specific on this immensely important topic, dividing for each insect first of all, then in addition to the above, barriers (mud & others), citronella, deet, clothing or modification of clothing, use of fire, shelter building against insects, Vitamin B, Vitamin E, skin-so-soft, extracts of plants, using dragonflies, etc.

>  
> This could be extended to garden/farming practices which reduce insect  
> damage.

I suggest that this subject would be out of bounds for this list, since agriculture does not really relate to primitive wilderness survival skills in the short term and would perhaps lead us too far astray.

> --  
> Sincerely,  
> Barent  
> Duty, Honor, Country

Thanks, Barent, for suggesting these incredibly interesting threads, and I am looking forward to pursuing it with the group in specific areas of interest. By the way, thank you everyone for renaming subject headers to reflect content so accurately in the past while, it is much easier to follow threads now.

X-Mozilla-Status: 0001

Andre's recent post reiterating topics for discussion brought up the subject of protection from insects, something I have often had need of and never found an entirely satisfactory solution to. Neesmuk had a solution of berries (durn it I can't find the dang thing in the book) and turpentine that he painted on his body which protected him from black flies and I remember being told by the guide at ? (was it Jamestown?) that the Native Americans (NAs) were not quite so dark skinned but after long exposure to the formula which they painted on their skin to protect them from various insects the skin would be dyed a darker color. This is fascinating to me but the best I have found is a combination of liberal applications of DEET and ingestion of above average quantities of vitamin B (various). Where I live we also have chiggers and ticks as major as major pests as well as mosquitos (much diminished since the early '60s) and various flies.

I see this topic as having 3 major threads:

1. Topically applied solutions for use as repellants.
2. Dietary supplements.

3. Botanical environmental additives (hanging of plants in you immediate area to discourage pest activity). Marigolds?

This could be extended to garden/farming practices which reduce insect damage.

Nessmuk's formula is as follows:

3 oz pine tar  
2 oz castor oil  
1 oz pennyroyal oil

Simmer together over a slow fire (low heat) and bottle. Rub in thoroughly and liberally at first. After establishing a good "glaze" a little rplenishing from day to day will suffice.

This is from: Wood Craft by "Nessmuk" (George W. Sears), Dover Publications, Inc., New York, 1963, Library of Congress Catalog Card Number 63-21680. I am sorry, no ISBN.

This was purchased for me in 1963 or 1964 by my Aunt, Virginia Parslow Partridge who at the time worked at the Farmer's Museum in Cooperstown, NY. She has lectured on textile arts and is a leader in pursuing the family geneaology. With family like this it is no wonder that these things fascinate me!

You mean those biting little buggars? Sure go ahead and try it. My question is, how to you get the spit up?

If my memory serves me;

Simply stir them up till they go crazy, then hold your hand as close as = possible for a minute or two (with out getting in their "range" and = keeping clear of blades of grass they could use to climb up on) And = apparently their "spit" will reach your hand. Then you can rub your hand = on exposed areas. I'm going to guess that this spit is used to repel ant = eating organisms.

Its all fun til and ant spits in your eye

Have a great day

Hi all,

Caught this message in the tracker archives and was wondering if anyone had any scientific knowledge or sources about this subject. I've heard about this a lot, and my personal experimentation does not lead me to any positive conclusions. I already know there are many opinions from both sides, and I don't need more of those, but now I'm looking for scientific data on this. Anyone?

Thanks for your help.

AndrÈ

Greetings from Thunder Bay

I talked to Jim Smithers, he was surprised that I brought up your name and mentioned that you joined them on part of their Mackenzie expedition. My plant books are in deed back home in Ottawa. The natural repellants from memory are:

Cedar-the smoke of leaves or bark in shelters to rid insects and a solution made from the leaves and bark to apply exturnally. The tannin may die skin if used in strong solution. Plantain as mentioned earlier when eaten after a while tends to act as a natural odour repellant. There are various plants to take the sting/itch away (exturnally only)also like Jewelweed (spotted touch me not). I believe these plants work but I would not take my word for it- I have tried them and they seem to work but it would be better to get such info right from the book to be safe. Have you tried any with success? I have a small collection (18 or so) of medicinal/edible books at home that touch on various interesting uses. Tom Brown I think mentions the above uses in his books, thats probably where I remember it from (Wilderness Survival, Living with the Earth and Wild medicinal plants). Sorry I could not provide a better list at this time. Best wishes

Chad

> How much plantain, and what part of the plant were you eating?

I find that eating two plantain pods a day keeps the bugs away. I had a wonderful chance to test the effectiveness of plantain when my wife and I went for a walk by a lake. She didn't eat plantain and was swarmed by mozzies, I ate it and didn't even get buzzed.

According to the reference "Edible and Medicinal plants of the Rocky Mountains" by Terry Willard, chewing plantain root will alleviate toothache.

In Tom Browns "Edible plants" book he says that the leaves taste great when boiled and can be eaten raw.

Plantain is also well respected for its healing and bandaging qualities. The leaves are large enough to cover many wounds. Crushed or chewed plantain leaves make an excellent poultice because they contain a natural antiseptic, slow blood flow and promote healing.

According to the book "Ethnobotony of the Thompson Indians" by Nancy J Turner et Al (Published in 1970 by the Museum of British Columbia) the tribes in this region used the plant as follows:

- 1) As a poultice of chewed leaves was applied over carbuncles, sores and hemorrhoids
- 2) The leaves were cooled and then applied to sores
- 3) A decoction of the leaves was used as a body wash

The native indians call the plant Plantago, which means "White mans footprint". They believed that it grew where ever a white man had walked.

In this they were absolutely correct - Plantain is not native to North America and was introduced from Europe by the settlers.

Tom Brown states that a decoction of the tea (45 minute steep) is an effective mouthwash for coldsores, sore gums and toothache. A weak tea is a good cough remedy and breaks up congestion. A wash of the tea is effective in promoting scarless healing and reducing blood flow from minor wounds.

(As a side note, my wife suffers from cold sores. A mountain guide advised her to rub behind her ears when she felt one coming on. This apparently stimulates the glands in the head to produce an antibiotic. I can tell you from personal experience that it does indeed help prevent cold sores.)

For those interested, check out your provincial or state museum for

information on local ethnobotany and native technologies. I find it quite exciting to read about a local plant and then go out to find it. It's only by finding and using the plants that the knowledge truly sinks in.

BTW, does any one know if Nancy J Turner is still around? I'd love to ask her some questions about her work.

Regards

Kevin Bennett

AB - A plant recently introduced into North America as the citrosa, Pelargonium citrosum ('Van Leenii'), has been marketed as a biological repellent against mosquitoes. Citrosa is claimed to

repel

mosquitoes within a 10 ft.2 (0.93 m2) area due to a continuous fragrant release of citronella oil. The total essential oil yield was 0.2 +/- 0.1% from fresh plant material. Chemical analysis by

the

authors revealed that combined essential oils of fresh greenhouse- and field-grown citrosa have 35.4 +/- 6.2% geraniol, 10.4 +/- 1.6% citronellol, 8.9 +/- 2.0% isomenthone, and 6.8 +/- 3.8% linalool. Both the morphology and essential oil of citrosa fall within the Pelargonium x asperum hybrid complex and are similar to 'Rose',

the

commercial rose geranium. No character of morphology or essential oil of a Cymbopogon species yielding commercial citronella oil

could

be detected in the citrosa. The effectiveness of the citrosa as a

repellent against field populations of spring Aedes spp.  
mosquitoes

was evaluated and compared with a 75% deet  
(N,N-diethyl-3-methylbenzamide) formulation. Deet provided > 90%  
reduction in mosquitoes biting subjects for up to 8 h  
post-treatment. There was no significant difference between  
citrosa-treated and nontreated subjects.

Ive read that in some places the folks always take a small dog or pig to bed with them.. the idea being that the body temp on the beast is higher, attracting the mosquitos and letting them get a good nights sleep.

thus one perhaps could come up with various thermal and chemical decoys.

rather than repel the mosquito .. attract it to some place else ??

At the hospital we use a dry chemical to absorb CO2 from pulmonary function  
machines. A little of this in a scarf wrapped around your face might make

you invisible.

While traveling in Wales, I learned the reason some people call the bathroom -- Cloak Room. Back in the days of Castles, people would 'clean' their cloaks of ticks and other pests by hanging them in the 'Cloak Room.' The bugs would jump off of their cloaks and onto the piles of steamers. [The original Steamer Cleaner!]

Maybe it's just me but, I wouldn't recommend sleeping next to a pile. :-)

Love & Health,  
Rees

According to "science news" mosquitoes are attracted to the CO2 in your breath and locate your body by it's gas trail. chew feen-a-mints, that will give them something to smell!

AB - Diel patterns of human host attack by *Aedes albopictus* in the  
laboratory were studied in relation to mosquito body size, age,  
parity, and time of day. Analysis of responses in 10-, 15-, and  
20-day-old females indicated a significant main effect due to time  
of observation in the diel period, as well as significant time x  
parity and time x age interactions. The distribution of mean host  
attack responses during the diel period was bimodal with  
approximately 70% of all activity during photophase (0800-2000 h);  
attack rates were highest in the morning (0800 h) and evening  
(1400-2000 h) and lowest between 0200 and 0600 h. The diel pattern  
of attack responses was bimodal for nulliparous and parous  
females,

but parous females were more active than nulliparous females  
between

1400 and 2000 h. This pattern became increasingly bimodal during  
photophase, as mosquitoes aged, regardless of mosquito body size

or

parity. Variations in host avidity patterns between young and old females suggest that mosquito repellent bioassays initiated early

in

the day, that last > or = 6 h, or that use young females (approximately 5 days old) overestimate the protection period of deet against mosquitoes > 10 days old.

MH - Thailand

AB - Laboratory and field tests of the repellents diethyl methylbenzamide

(deet), 1-(3-Cyclohexen-1-yl-carbonyl)-2-methylpiperidine (AI3-37220), and (2-hydroxymethylcyclohexyl) acetic acid lactone (CIC-4) were conducted against *Anopheles dirus* Peyton & Harrison, the principal malaria vector in Thailand. In the laboratory, *An. dirus* was more sensitive to CIC-4 than either AI3-37220 or deet.

The

duration of protection provided by each repellent in laboratory tests increased with higher concentrations of repellents and when exposed in cages containing fewer mosquitoes. A field study in Chanthaburi Province, southeastern Thailand, during November 1993 tested 25% (wt:wt) ethanol solutions of each repellent against An. dirus. In contrast to the laboratory experiments, protection provided by AI3-37220 was significantly better than either deet or CIC-4 and there was no significant difference between deet and CIC-4. Protection provided by deet and CIC-4 fell to below 95% 2 h after repellent application, whereas AI3-37220 provided > 95% protection for 4 h. The protection provided by all repellents fell to < or = 65% 7 h after repellent application.

Wouldn't it be fairly straight forward to conduct your own study using a large group of people on a long outing? Divide them into fairly matched pairs and give one group vitamin B (its B 6 isn't it?) at a precise dosage (x mg/kg body wt) continuously for several days while the others act as controls. The outcome variable, number of bites per day, is pretty easy to measure. And you could even have fun counting if you had the right partner! If there were a lot of bites you could maybe total the welt areas. Then a simple paired t-test and voila, your answer. You might even publish it. I offer this only half in jest.

As far as I know from all the research I have done so far, there is no=20  
confirmed scientific evidence of effects of diet of any kind as causal=20  
to number of insect bites. Vitamin B we hear a lot about, but the=20  
problem with reports such as: "and I got no bites while my wife got=20  
tons" has no scientific merit because you don't know if the Vitamin B=20  
was the cause or whether it is something else. How do you know you=20  
would have had any more bites without the vitamin B? In order to=20  
establish a causal relationship here, you would have to control all of=20  
the other variables which could potentially be involved.

It's the first time I hear about nuts having an effect on bugs. I doubt=20

very much that this would be true. However, I would love to be proved=20 wrong.

Primitive cheers,

This has probably been done already. Unfortunately it has also most likely been done by the military, in which case the research might be unavailable or hard to find. But who knows? [1]

Another setup might be:

\* Double blind (neither the test subject nor the experimenter knows ahead of time which is placebo and which is the "test substance". hard to do with nuts, but...)

\* Have a cage with a known number of mosquitos, expose a known amount of body (e.g. the arm, actual area can be rougthly calculated) for a known duration. Count the number of bites.

\* Use each test subject with all test substances, but in randomized order (double blind, naturally).

\* Repeat as many times as needed to have (statistical) confidence in the experiment.

\* Write up and publish in some more or less obscure journal.

/Par

[1] I just did a search in Medline: 107 hits (1966-present) on the combination of mosquitos and repellent, I'll look throught them to see if there is anything usefull. If anyone (a) can't access medline themselves, and (b) want the whole dump (referenses and abstracts), I can mail it to interested individuals. \*Not\* the list.
